The INFOConnect CASL Script Language Guide is designed to assist you in creating and implementing macros that enhance communication between your PC and host. It introduces CASL, the Common Accessory Script Language. This guide explains how to use CASL with Accessory Manager.

This preface contains the following sections:

Audience ........................................................................... xiv
Documentation Conventions ........................................... xv
Abbreviations .................................................................... xviii
Related Documentation ..................................................... xix
About This Guide

Audience

This guide is written for Accessory Manager users who want to write CASL macros. It begins with conceptual information so that the inexperienced programmer can learn the hows and whys of writing macros. The guide provides reference material on implementing each macro element. This reference material also includes details for the sophisticated application developer.

If you are new to writing macros, you may benefit from first reading Chapter 1, “Introducing CASL.”

Before reading this guide, you should understand general concepts for Accessory Manager.
About This Guide

Documentation Conventions

The following documentation conventions are used in this guide:

- All text that you type on a screen or messages and prompts that appear on the screen are displayed in this type style.
  This type style also is used for CASL macro text.

- Square brackets ([ ]) indicate that the argument is optional. The following example illustrates the notational use of square brackets:
  
  `alarm [integer]`

  In this example, the argument `integer` is optional.

- Words or characters in braces ({ }) represent multiple arguments from which to choose. The choices are separated by a vertical line, as shown in the following example:

  `genlines {on | off}`

  In this example, there are two choices: on and off. These are the only possible choices.

- An ellipsis (...) can have one of several meanings.
  - If the ellipses occurs at the end of a line, it indicates that the line is continued on the following line, or that the code continues but no additional data is shown, as in these examples:
    `[edittext x, y, w, h, init_text, ... str_result_var [, options]]`
    `if arg(1) = "barkley" then ...`
  - If the ellipses occurs on a line of its own, it indicates that intervening lines of code have been omitted, as in the following example:
    `done = false`
    `while not done`
    `
    ...
    ...
    wend`
About This Guide

- If the ellipses follows an item in italics, you can repeat the previous item one or more times, as in the following example:

  digit ...  
  
  In this example, you can have just one digit, or you may have multiple digits. You must have at least one digit.

- If the ellipses follows an item in square brackets, you can repeat the item zero or more times, as in the following example:

  [, var] ...  
  
  In this example, var is optional. If you choose to use var as an argument, the ellipsis indicates that you can have multiple variables as arguments.

- Italic type is used in the following situations:
  - To show emphasis, as in, “Do not use the Copy command.”
  - To show that a word is a placeholder that stands for something else, as in the following example:

    delete filename

    In this case, you enter the actual file name rather than the word filename.

The following are some common placeholders:

- char (Integer)—The integer ASCII value of a character

- expression (Any)—More than one type of expression can be used here. Read the text to determine which is suitable.

- filename (String)—A legal file specification. You can use full path names, as well as wild card characters (where appropriate.

- filenum (Integer)—A file number. Range 1–8. These expressions are usually optional and must be preceded by a pound sign (#) if they are specified.

- time_expr (Integer)—An amount of time. You can use any numeric expression followed by ticks, seconds, minutes, or hours. If you do not specify a keyword, seconds is assumed.
About This Guide

- The word *PC* refers to any personal computer running Windows

- The word *host* refers to any mainframe, mini-computer, or information hub with which the PC communicates.

- File names are shown in all capital letters, as in INSTALL.EXE, unless a file name is part of a command. In this situation, lowercase letters are used to show that you do not have to enter the file name in all capitals.

Compiling a CASL Macro ................................................. 29
Running a CASL Macro .................................................... 30
About CASL

CASL is a scripting language that you can use to create macros that can interact with hosts, users, and other macros. The macros you develop can be simple or complex. For instance, you can create a simple macro that waits for a prompt from the host and then replies with a user ID and password. More complex macros can automate entire communications sessions or create custom dialog boxes that enable users to operate a host application without learning its commands.

While CASL is designed to simplify the process of communicating with other computers, it is not limited to that function. CASL is a full-featured programming language that can handle almost any task, including complex mathematical computations and the display of sophisticated dialog boxes.

CASL macros work with any emulator that runs within Accessory Manager. Any limitations that are specific to a particular emulator (such as ALC or EXTRA® Enterprise for Accessory Manager) are noted throughout this guide or the Readme file for the product.
Why Use Macros?

When you work in a data communication environment, you often have to perform the same functions over and over again to complete your daily activities. For instance, each time you open a session with a host, you have to type your logon ID and password.

You can eliminate the manual repetition of routine tasks by using macros to communicate with the host. You have to create and save a macro to be able to use it, but once you have done this, you will find it invaluable in saving time and effort in the future.

Using macros, you can do any of the following:

- Perform keystroke sequences
- Run another PC application
- Perform almost any function that can be performed using Accessory Manager, such as loading a QuickPad™
- Create dialog boxes so that you can request user input

In addition, creating and implementing CASL macros are not difficult tasks. Traditionally, developing applications and utilities that run in a communications environment required a complex programming language and an Application Programming Interface (API) to access the host. You also had to understand the underlying data communications link. CASL removes these obstacles. When you write a CASL macro, you do not have to concern yourself with the details of communication programming; CASL handles the communication interface.
Chapter 1  Introducing CASL

Creating and Editing CASL Macros

Creating a CASL Macro

You can create a CASL macro in two ways:

- Learn Mode—you perform the actions that you want to include in the macro, and Accessory Manager records those actions in a CASL macro file, which you can then edit if needed.

- CASL Macro Editor—you open the CASL Macro Editor and write the macro using the CASL script language.

Caution: CASL macro files have a size limit of 64K bytes.

Using Learn Mode

To create a CASL macro using Learn Mode, follow these steps:

1. With a session open, click Learn CASL Macro from the Tools menu.

   The CASL Macro Editor starts in a minimized state.

2. Perform the tasks that you want to include in the macro.

3. When you have finished, click Stop CASL Learn from the Tools menu.

4. When you are prompted about saving the CASL macro, do one of the following:

<table>
<thead>
<tr>
<th>To do this</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>Save the CASL macro</td>
<td>Click Yes, type a name for the macro in the File Name text box (you do not have to include a file extension), and click Save on the Save As dialog box. Note: In INFOConnect 9.1 and later, the CASL Macro Editor encrypts macros (and any related source files) during the save process if the Encrypt macros setting is selected in the Accessory Manager Global Preferences dialog box.</td>
</tr>
<tr>
<td>Not save the CASL macro</td>
<td>Click No.</td>
</tr>
</tbody>
</table>

If you need to edit the CASL macro, you can do so using the CASL Macro Editor. Refer to the online Help for Accessory Manager for detailed information.
Creating and Editing CASL Macros

Chapter 1  Introducing CASL

Using the CASL Macro Editor

To create a CASL macro using the CASL Macro Editor, follow these steps:

1. With a session open, click CASL Macro from the Tools menu.

2. Click New.

The CASL Macro Editor starts, displaying a window similar to the one shown below:

For information about using this editor, refer to the online Help.
Types of Macros

There are two main types of CASL macros:

- Online
- Offline

Online macros work while Accessory Manager is connected to a host. Usually, these interact with the host to automate all or part of a communications session. You can use online macros to log on to the host, or create a custom dialog box for interacting with a host application.

Offline macros do not interact with a host. For example, you can use an offline macro to display a list of hosts to which a user might want to log on.

**Note:** A session must be open for you to run either an online or an offline macro.
The Structure of Macros

CASL is flexible enough to accommodate most writing styles. If you have written computer programs before, you should be able to retain the same style you have used in the past.

In general, the contents of a macro include such items as comments, declarations, and directives. A comment documents a macro; a declaration defines a variable, an array, a procedure, or a function; and a directive specifies an action to be taken.

Comments

Use comments to explain what will happen when a segment of code is executed or to block out part of a macro that you do not want to execute. Comments are ignored by the macro compiler and do not take up any memory after a macro is compiled. So you can include many comments to document the flow of a macro.

Starting your macro with a comment header is good practice. This header should include your name, the creation date, and some explanation of its objective. An example of this type of comment is as follows:

-- Macro name: LOGON.XWS
-- Date: 6/24/2000
-- Author: John Doe

In this example, the double hyphen is used to indicate a comment. Chapter 2, “Understanding the Basics of CASL,” describes other notations you can use to designate a comment.

Declarations

Set up your declarations and assign values to them, if appropriate, immediately after the comment header. This will help you keep the declarations easy to find, as shown here:

-- Macro name: LOGON.XWS
-- Date: 6/24/2000
-- Author: John Doe
integer count, access_number
count = 1
access_number = NetID
The body of a macro, which follows the declarations, is made up of directives, or statements, that specify actions to be taken. You can structure your macro statements with one statement on a line, multiple statements on a line separated by colons (:), or a series of statements enclosed in braces ({}). The following example shows one macro statement on a line:

```casl
print "Hello!"
```

Chapter 2, “Understanding the Basics of CASL,” provides examples of how to write statements using the alternate structures.

To make your macro more readable and maintainable, you can indent statements that are part of a larger construct. Indentation, which is ignored by the compiler, is shown in the following example of a for...next construct:

```casl
integer count
for count = 1 to 10
  print count
next
```

As shown in the preceding example, you can also use blank lines to improve program readability.
The Elements of a Macro

Your macros can consist of many different kinds of language elements. The sample macro you develop in a later section contains examples of many of them. A brief description of the more commonly used CASL components follows.

**Statements**

Statements perform such functions as assignment of values, file input/output, file transfer, macro flow control, host interaction, window control, and communications session management. CASL statements are described in detail in Chapter 6, “CASL Language.”

**Variables**

Variables are elements that can store data. In your macros, you can use variables that you create and variables that are predeclared by CASL. CASL’s predeclared variables are described in Chapter 6, “CASL Language.”

**Constants**

Constants are elements that have a fixed value. Use the value directly in your macro.

**Expressions**

Expressions include arithmetic expressions, string expressions, relational expressions, and Boolean expressions.

**Labels**

Labels are named reference points in a macro. A label can be the destination of a goto statement or it can mark the beginning of a subroutine. Guidelines for using the label statement in a macro are presented in Chapter 6, “CASL Language.” Label scope rules are explained in Chapter 3, “Variables, Arrays, Procedures, and Functions.”

**Procedures and Functions**

Procedures and functions perform unique tasks. They differ in that functions return a value, and procedures do not. CASL provides built-in functions, which are predeclared. You can use these built-in elements as well as implement your own procedures and functions. See Chapter 6, “CASL Language,” for details.
Chapter 1  Introducing CASL

Keywords

Keywords make your macro more readable. CASL keywords are reserved for a particular use in your macro; for example, statement names and words that bind arguments are all reserved keywords. You cannot use keywords as names for your variables, functions, procedures, or subroutines. Chapter 2, “Understanding the Basics of CASL,” contains a table of the keywords reserved by CASL.
Designing a Macro

In the process of developing and implementing a more complex macro, the following is a typical development cycle:

- Design the macro.
- Write and edit the macro.
- Compile the macro and locate any compile errors.
- Fix the errors and compile again.
- Run the macro to be sure it works.
- Correct any problems.

Before you write a macro, you should map out what you want the macro to accomplish. This step in the development cycle is especially important when you create macros to use with communications programs. It is difficult to predict exactly what another computer will do during a communication session. Therefore, it is advisable to design your macro to handle any type of situation that may occur.

Your macro design can be as simple as a list of steps that outline the goals you want to accomplish. You can produce more detailed design plans by drawing flow charts. Listing goals and drawing flow charts are not always necessary, but they can often save you hours of work later.
Chapter 1  Introducing CASL

Sample: A Basic Logon Macro

In this sample, you send a logon sequence to MCI Mail. The example assumes that your macro will run in a trouble-free environment, that is, it will not encounter errors or slow responses from the host.

/* This macro shows how to display messages and send a user ID and password to MCI Mail. */

-- Macro name: SAMPLE1.XWS
-- Created: 6/24/2000 - Jane Smith

/* Display a message on the status line to tell the user what is going on. */

message "MCI Mail auto-logon in progress"

/* Send a carriage return (CR) to get MCI's attention and then send the logon user ID and password. */

reply -- Send a CR
wait 2 seconds -- Wait for prompt
reply userid -- Send User ID
wait 2 seconds -- Wait for prompt
reply password -- Send password

message 'MCI auto-logon complete'-- Tell the user

end -- End the macro

Describing the Purpose of the Macro

The macro begins with a comment describing the purpose of the macro.

/* This macro shows how to display messages and send a user ID and password to MCI Mail. */

This is a block comment, which is enclosed in the symbol pair /* and */. When you start your macro with an explanatory comment, you assist other macro writers who later need to understand your work.
Documenting the Macro’s History

The sample macro comment header also provides a history of the script’s development, including the macro file name, the creation date, and the author’s name. This comment begins with a double hyphen, which tells the macro compiler that this is a line comment. Line comments do not require an end-of-comment symbol.

-- Macro name: SAMPLE.XWS
-- Created: 6/24/2000 - Jane Smith

After subsequent macro modifications, the header might appear as follows:

-- Macro name: SAMPLE.XWS
-- Created: 2/14/2000 - Jane Smith
-- Modified: 5/10/2000 - John Doe

The additional comments record the history of the macro development.

Displaying a Message

The first line of code displays a message that tells the user what is occurring. To display this type of simple message, use the message statement.

message "MCI Mail auto-logon in progress"

Using String Constants

As you can see in the message statement, the words that are displayed are enclosed in quotation marks. A character string enclosed in quotation marks is called a string constant. When you use CASL, you must enclose all string constants with quotation marks. You can use either double quotation marks, as shown in the preceding example, or single quotation marks, as shown in the script’s second message.

message 'MCI auto-logon complete'

Be sure to use the same type of beginning and ending quotation marks.
Chapter 1 Introducing CASL

Establishing Communications with MCI Mail

To establish communications with MCI Mail, use the reply statement.

reply

When you use the reply statement without an argument, a carriage return is sent to the host. This alerts the host to prompt for a user ID.

Waiting for a Prompt from the Host

After you send a carriage return to the host, you should wait for a brief period to allow the host to send a prompt.

wait 2 seconds

The wait statement causes the macro to pause for two seconds to allow the host to respond with the first prompt. The amount of time to wait depends on your operating environment and the host.

Sending the Logon Sequence

Once you have set up the connection, you can send your user ID and password. To do this, use two reply statements—one to send the user ID and one to send the password. Be sure to wait for a brief period before sending the second reply statement to allow time for the host to send the password prompt.

reply userid
wait 2 seconds
reply password

Using CASL Predeclared Variables

CASL provides a rich set of predeclared variables, which include system variables and module variables. The sample macro contains two of the predeclared system variables: userid and password.

userid and password are set up as system variables to make it easy for everyone to use CASL macros and also to help maintain security. You can define these variables from Accessory Manager by clicking Session Preferences from the Options menu and clicking the CASL Macro tab. You can also modify these variables in a macro. The sample macro uses the predefined contents of the variables to send the user ID and password to MCI Mail.

reply userid
reply password
Chapter 1  Introducing CASL

Using Keywords

In the wait statement, you find the word seconds.

wait 2 seconds

This word is one of many CASL keywords that make your macro more readable and flexible. Use the keywords only where specified in the various language elements.

Ending the Macro

There are several ways to end a macro, depending on the reason for its termination. The most common way is to use the end statement, as shown in the sample macro.

The end statement brings the macro to an orderly conclusion. Other CASL statements, such as halt, quit, and terminate, cause related macros, sessions, or Accessory Manager to end also. These statements are discussed in detail in Chapter 6, “CASL Language.”

Using Comments and Blank Lines

Throughout the sample macro there are comments explaining what the programming code is to accomplish. Some of the comments are block comments, which are enclosed in the symbol pair /* and */.

/* Display a message on the status line to tell the user what is going on. */

Other comments are line comments.

-- Macro name: SAMPLE.XWS
reply -- Send a CR

As you can see, the line comments begin with a double hyphen (--) . You can use both of these commenting methods in your macro.

The sample macro also shows how to use blank lines to make a macro more readable. You can use blank lines almost anywhere in your macro.
Sample: Verifying the Host Connection

The previous sample macro assumed that MCI Mail responded to the initial carriage return within the expected time frame. But this may not always be the case. The following sample macro shows how to verify that communications have, in fact, been established.

/* This macro shows how to display messages and send a user ID and password to MCI Mail. It also verifies that the MCI Mail connection is active. */

-- Macro name:SAMPLE2.XWS
-- Created:6/24/2000 - Jane Smith
-- Modified:6/25/2000 - Jane Smith (Added code to check for the "port:" prompt.)

/* First, define the required variable. */

integer i

/* Display a message on the status line to tell the user what is going on. */

message "MCI Mail auto-logon in progress"

/* Try to get MCI Mail's attention by sending a carriage return (CR) until the "port:" prompt is received. */

i = 1
while i <= 10
    reply -- Send a CR
    wait 2 seconds for "port:" -- Wait for prompt
    if not timeout then -- If no timeout
        goto LOGIN -- Branch to LOGIN
to -- wait for prompts
    }
i = i + 1 -- Increment counter
wend

/* Could not get MCI Mail's attention. Tell the user and hang up. */
alert "System not responding - Logon canceled.", ok
bye -- Disconnect
end -- End

label LOGIN
wait for "name:" -- First prompt
reply userid -- Send user ID
wait for "password:" -- Next prompt
reply password -- Send password
message 'MCI auto-logon complete' -- Tell the user
end -- End the macro

Declaring Variables

As in the first sample macro, this sample starts with a description of its purpose and an outline of its history. (The comment header is updated to reflect a modification to the original macro.) This macro adds functionality that takes control in the event that MCI Mail does not respond to the initial reply statement.

First the macro declares a variable that it will use as part of a conditional expression that determines how long to perform a task. As part of the task, it sends a carriage return to establish communications with MCI Mail and then waits for the expected character string from the application. If a time-out does not occur, the macro branches to a different location to send the logon sequence to the application. If, however, communications cannot be established after ten carriage returns are sent, the macro alerts the user to the failure, disconnects the session, and ends.

To declare a variable, specify a data-type identifier and a variable name. In the sample macro, a variable named i, with a data type of integer, is declared.

integer i

This macro uses only one variable. If your macro contains multiple variables of the same data type, you can declare all of them on the same line.

integer i, tries

Note: If the variables have different data types, you must declare them on separate lines.
Chapter 1  Introducing CASL

Initializing Variables
The macro compiler initializes an integer variable to a default value of 0. To initialize the variable to a different value, use the equal sign (=). In the sample macro, the i variable is initialized to the value 1.

\[ i = 1 \]

Performing a Task While a Condition Is True
To execute statements repeatedly while a condition is true, use the while...wend construct. If the condition is initially false, the statements are not executed at all. This macro uses the while...wend construct to control the process of connecting to MCI Mail.

\[
\text{while } i \leq 10 \\
\text{ reply} \\
\text{ wait 2 seconds for "port:"} \\
\text{ if not timeout then} \\
\{ \\
\text{ goto LOGIN } \\
\} \\
\text{ i = i + 1 } \\
\text{ wend}
\]

The statements between the while and wend are continually executed until the condition \( i \leq 10 \) is no longer true. Then control passes to the statement following the wend.

Using a Relational Expression to Control the Process
Expressions that use relational operators (such as < and =) are called relational expressions. When you use these operators, the result is always a Boolean value (true or false). In this macro, the relational expression \( i \leq 10 \) is used to determine how many times the while...wend construct is performed. As long as the condition is true, the statements within the construct are executed. When the condition is no longer true, the statement following the wend is executed.

Waiting for a Character String
If you want your macro to wait for one specific text string, use the wait statement. This sample macro waits for the character string "port:" to ensure that a connection with MCI Mail is established. To prevent the macro from waiting forever, a duration time of two seconds is specified.

\[
\text{wait 2 seconds for "port:"}
\]

You can determine if a time-out occurred before the character string arrived, as explained in the next section.
### Checking if a Timeout Occurred

Use the `if...then` construct and the `timeout` system variable to determine the outcome of the `wait` statement.

```casl
if not timeout then
{
  goto LOGIN
}
```

The `timeout` system variable is either true or false indicating whether the last `wait` statement timed out. In this macro, `timeout` is true if the `wait` statement exceeds the time specification of 2 seconds before finding the "port:" text string.

When you use the `if...then` construct, the statement(s) following the `then` are executed only if the condition is true. In this macro, the `goto LOGIN` statement is executed if a time-out does not occur; if a time-out occurs, the `i = i + 1` statement is executed.

### Testing the Outcome with a Boolean Expression

The condition you use in an `if...then` statement is usually a Boolean expression. Boolean expressions return either true or false. Your Boolean expressions can be simple, as shown in this macro:

```casl
if not timeout then
```

You can also use more complex expressions, involving multiple conditions with Boolean operators, as shown in the following example:

```casl
if var1 >= 12 and var2 <= 5 then
```

In the sample macro, if the Boolean expression is true, the macro transfers control to a logon routine, which is located in a different part of the macro, as explained in the next section.

### Branching to a Different Macro Location

Sometimes it is preferable to handle a certain piece of coding logic in a separate part of a macro. To branch to this location, you can use the `goto` statement.

```casl
if not timeout then
{
  goto LOGIN
}
```
To enable the macro compiler to know where to branch, you must supply a label name in the goto statement. In the sample macro, the label LOGIN is used to indicate the location where the next logical piece of code is located. The actual location is identified by the label statement.

```plaintext
label LOGIN
```

CASL provides another statement that allows you to branch to a label: gosub...return. For detailed information about this statement, refer to “gosub...return (statements)” on page 218.

### Continuing the Logon if the Connection Is Established

If the macro receives the "port:" prompt before a time-out occurs, it sends the logon sequence to the host, displays a message, and ends.

```plaintext
label LOGIN
wait for "name:"
reply userid
wait for "password:"
reply password
message 'MCI auto-logon complete'
end
```

If the "port:" prompt does not arrive in time, the macro increments the while...wend conditional counter.

### Incrementing a Counter Using an Arithmetic Expression

The number of times the while...wend construct is performed depends on the value in the variable i. To increment that value, you must use an arithmetic expression. Arithmetic expressions consist of numeric arguments and arithmetic operators. In the sample macro, the addition operator, which is a plus sign (+), is used to add 1 to i.

```plaintext
i = i + 1
```

The counter continues to increment until the host sends the character string "port:" or until the counter's value no longer satisfies the condition for the while...wend construct (i <= 10). If the host does not respond, the macro alerts the user to the failure.

### Alerting the User if the Connection Failed

In general, the sample macro uses the message statement to inform the user of current events. A message, which is displayed without a dialog box, does not require any user intervention and is replaced by other messages.
To display information to which the user must respond, use the alert statement. The alert statement displays a message in a dialog box, which requires the user to choose a command to exit the dialog box. In the sample macro, the alert statement provides an OK button for the user.

```
alert "System not responding - Logon canceled.", ok
```

The macro pauses at the alert statement until the user clicks OK.

**Disconnecting the Session**

If the connection with MCI Mail cannot be established, the macro uses the bye statement to end the session. The bye statement immediately disconnects the current session.

**Using Indentation**

As you can see, some of the lines of code in the macro are indented. For instance, the code within the while...wend loop is indented.

```
while i <= 10
  reply
  wait 2 seconds for "port:"
  if not timeout then
    goto LOGIN
  i = i + 1
wend
```

Indentation is not required, but it helps to make your macro more readable. If indentation was not used in the sample macro, it would be difficult to determine which lines of code applied to the while...wend construct.
Using Braces with a Statement Group

You can use braces to enclose one or more statements that belong together. In the sample macro, braces enclose the \texttt{goto} statement that follows the if...then statement, indicating that the \texttt{goto} statement is part of the if...then construct.

\begin{verbatim}
if not timeout then
{
   goto LOGIN
}
\end{verbatim}
Sample: Controlling the Entire Logon Process

In the previous examples, the sample macros did not verify the logon prompts sent by the host and therefore did not take corrective action if a prompt never appeared. In this macro, you can see how to use the watch...endwatch construct within a while...wend loop, to wait for any one of multiple character strings from the host and then take appropriate action based on the string that is received. The programming logic in this macro gives you greater control over the sequence of events that may occur when communicating with your host.

/* This macro shows how to display messages and send a user ID and password to MCI Mail. It also verifies that the MCI Mail connection is active and uses the watch statement to verify that the logon sequence is successfully sent to the host. */

-- Macro name: SAMPLE3.XWS
-- Created: 6/24/92 - Jane Smith
-- Modified: 6/25/92 - Jane Smith (Added code to -- check for the "port:" prompt.)
-- Modified: 7/02/92 - John Jones (Added code to -- check for specific logon
-- prompts.)

/* First, define the required variables. */

integer i, tries

/* Display a message on the status line to tell the user what is going on. */

message "MCI Mail auto-logon in progress"

/* Send a carriage return until the "port:" prompt is received. */

i = 1 -- Initialize
-- variable

while i <= 10 -- Perform while i is
-- less than or equal
-- to 10
reply -- Send CR
wait 2 seconds for "port:" -- Wait for prompt
if not timeout then goto LOGIN -- If no timeout,
Chapter 1 | Introducing CASL

-- branch to LOGIN
-- to check next
-- prompts
i = i + 1
wend

/* Could not get MCI Mail's attention. Tell the user and hang up. */

alert "System not responding - Logon canceled.", ok
bye
-- Disconnect
end
-- End the macro

label LOGIN
-- Branch-to location

/* Try to log on to MCI Mail for 50 seconds. If not successful, disconnect the session and exit. */

tries = 1
-- Initialize
-- variable
while online and tries < 5
-- Perform while both
-- conditions are
-- true
watch 10 seconds for
-- Wait for any one
-- of the following
-- host responses
quiet 2 seconds : reply
"name:" : wait 5 ticks : reply userid
"password:" : wait 5 ticks : reply password
"sorry, inc" : wait 5 ticks : bye : ...
message "Unable to log on." : end
"COM" : alarm 1 : message "MCI * + ...
"Mail auto-logon complete." : end
"call Customer Service" : ...
alert "Connection refused.", ok : end
endwatch
tries = tries + 1
wend

if tries < 5 then
-- If not successful
{
bye
-- Disconnect
alert "Lost the connection.", ok
-- Tell the user
}
end
-- End
As in the second sample macro, which verified the MCI Mail connection, this macro contains the appropriate lead-in comments, attempts to establish communications with MCI Mail, waits for the "port:" prompt from the host, and branches to a different location to handle the balance of the logon process. At this point, however, this macro uses a more comprehensive technique to ensure that it sends the correct logon responses to the host.

Based on two controlling conditions (the macro is online and tries is less than 5), the macro repeatedly watches for one of several host responses to arrive. If either of the two controlling conditions becomes invalid, the logon process terminates. Otherwise the macro responds appropriately to whichever host prompt or message it receives.

**Performing a Task while Multiple Conditions Are True**

In the previous sample macro, the while...wend construct contained one relational expression that determined how many times the while loop was repeated. This macro uses two conditions to determine the duration of the loop: the result of the online function and the result of a relational expression.

\[
\text{while online and tries < 5}
\]

As long as both conditions are true, the statements in the while...wend construct are repeatedly executed. If either of the conditions becomes false, macro execution continues with the statement following the wend.

The online function returns true as long as the macro is online to the host. The relational expression tries < 5 returns true as long as tries is less than 5. Since the variable tries is initialized to 1 before the while loop and then is incremented by 1 each time the loop is executed, the while...wend construct will be repeated a maximum of four times. It may be repeated fewer than four times, depending on what happens while the macro is watching for one of several host responses.

**Watching for One of Several Host Responses**

If you know that the host may send one of several different prompts, use the watch...endwatch construct with multiple conditions to watch for each possible prompt or message. The sample macro watches ten seconds for six potential conditions.
Write each watch condition as a separate entity. When one of the conditions occurs, the statements for that watch condition are executed and the watch...endwatch construct ends. If the ten-second time-out expires before a watch condition is satisfied, processing returns to the while...wend construct. If both of the while conditions are still true, the macro executes the watch...endwatch construct again.

You need to write the actual watch statement only once for all of the watch conditions.

watch 10 seconds for

Each watch condition, along with its accompanying directives, is specified individually. These conditions are discussed in the paragraphs that follow. As you can see in this macro, the watch conditions are followed by a colon (:). The colon is required.

A Quiet Connection

The first watch condition waits for the connection to be quiet for two consecutive seconds.

quiet 2 seconds : reply

If this condition is met, the macro sends a carriage return to MCI Mail and processing returns to the while...wend construct. If the macro is still online and tries is less than 5, the watch...endwatch construct is executed again.

The "name:" Prompt

The second watch condition looks for the character string "name:"

"name:" : wait 5 ticks : reply userid

If the macro receives the "name:" prompt, it waits five ticks (a tick is one tenth of a second) and then sends the contents of userid to MCI Mail. If the macro is still online and tries is less than 5, the watch...endwatch construct is executed again.

The "password:" Prompt

If the host sends the "password:" prompt, the macro executes the statements associated with the third watch condition.

"password:" : wait 5 ticks : reply password
Chapter 1  Introducing CASL

After a brief wait of five ticks, the macro sends the contents of the system variable password to MCI Mail and then processing returns to the while...wend construct. The watch...endwatch construct is executed again if both of the while conditions remain true.

The "sorry, inc" Message

The fourth watch condition looks for the character string "sorry, inc".

"sorry, inc" : wait 5 ticks : bye : ...
    message "Unable to log on." : end

If the macro receives this message, it waits five ticks, disconnects the session, displays a message for the user, and ends. Processing does not return to the while...wend construct if this character string is received.

The "COM" Message

If the host sends the "COM" message, the statements associated with the fifth watch condition are executed.

"COM" : alarm 1 : message "MCI " + ...
    "Mail auto-logon complete." : end

In this case, the macro recognizes that the logon process has completed successfully. Therefore, it sounds an alarm to get the user's attention, displays an appropriate message, and ends.

The "call Customer Service" Message

If the macro receives the "call Customer Service" message, it executes the statements associated with the last watch condition.

"call Customer Service" : ...
    alert "Connection refused.", ok : end

The macro displays a dialog box and waits for the user to click OK; then it ends.

Sounding an Alarm

To get the user's attention, you can use the alarm statement to make the PC emit a sound. This macro uses the alarm statement, with an argument of 1.

"COM" : alarm 1 : message "MCI " + ...
    "Mail auto-logon complete." : end
The `alarm` statement argument determines the type of sound that the PC makes. In this case, an argument of 1 specifies that the PC should play the .WAV file associated with the SystemAsterisk key in the Windows Registry. For more information about alarm sounds, refer to “`alarm (statement)`” on page 128.

### Using the Line-Continuation Sequence

To write a directive that continues on another line, you must use the line-continuation sequence ( ... ) at the end of the line to be continued. You can see an example of this in the sample macro.

```
"sorry, inc" : wait 5 ticks : bye : ...
    message "Unable to log on." : end
```

**Note:** You can skip using the line continuation sequence and keep the entire statement on one line. However, the statement may be too long to fit in your editor window, and you will have to scroll to the right and left to see the entire line.

If you have a string constant that is too long to fit on one line, you can break the string into segments and use the line-continuation sequence to indicate the string continues on another line. You must enclose each string segment with quotation marks and use the string concatenation operator (+) to join the strings.

```
"COM" : alarm 1 : message "MCI " + ...
    "Mail auto-logon complete." : end
```
Chapter 1  Introducing CASL

Compiling a CASL Macro

Once you have created and saved a CASL macro, you should compile it to determine possible syntax errors. The compiler converts your source macro into a binary, machine-readable form and reports any errors that it detects. The compilation process takes only a small amount of time. When you have corrected all of the syntax errors, you can run the macro.

There are two types of macro files:

- Source file (.XWS), which you create and edit
- Executable file (.XWC), which is created when you compile your macro

Procedure

To compile a CASL macro, follow these steps:

1. If the CASL macro that you want to compile is not already open, open it.
   - From an Accessory Manager session, click CASL Macro from the Tools menu, click the desired .XWS file, and click Edit.
   - From the CASL Macro Editor, click Open from the File menu and double-click the desired .XWS file.

2. From the Macro menu, click Compile.

3. If any compilation errors occur, correct the errors.

4. Repeat steps 2 and 3 until your macro compiles without errors.

Note: The macro compiler automatically compiles any macro you run if the macro has not already been compiled or if the most recent version of the source macro is newer than the compiled version. However, you should compile your macros before trying to run them to ensure that all syntax errors are corrected.
Running a CASL Macro

You can run macros at any of the following times:

- When you start Accessory Manager (application start-up macro)
- When you open a session (session start-up macro)
- When you click CASL Macro from the Tools menu, click the desired macro, and click Run
- When you click a toolbar or QuickPad button, press a key, or double-click a HotSpot that has been configured to run a macro
- When the left mouse double-click has been configured to run a macro with the same name as the word under the mouse pointer
- When you click Run from the CASL Macro Editor’s Macro menu

For detailed information about these procedures, refer to the online Help for Accessory Manager.
Understanding the Basics of CASL

- Type Conversion ................................................... 54
- Compiler Directives .............................................. 56
- Reserved Keywords .............................................. 58
Statements

Statements specify an action to be taken. You can write the statements in any of the following ways:

- One statement to a logical line, as shown in the following example:
  
  `activate`

- Multiple statements to a logical line with a colon (:) between each statement, as shown in the following example:
  
  `wait for "Enter user ID:" : reply userid
   wait for "Enter password:" : reply password`

- A series of statements enclosed in braces ({ }), as shown in the following example:
  
  `if online then
   {
     reply userid
     wait for "?"
     reply password
   }

Line Continuation Characters

You can continue a statement on the next line by placing line continuation characters ( ... ) at the end of the previous line. You can use the line continuation sequence anywhere in a macro except inside quotation marks. The following example shows how to use the line continuation characters:

`proc add_integers takes integer one_num, ...
   integer second_num`

The line continuation sequence after the word `one_num` indicates that there is more information to follow.
Chapter 2  Understanding the Basics of CASL

Comments

Use comments to document your macro. Comments are useful for maintaining, modifying, or debugging the macro in the future.

You can add two types of comments to a macro:

- Block comments
- Line comments

**Block Comments**

When you want to add a block of comments, enclose the comment text with the symbol pair /* and */ as shown in the following example:

```/* This macro logs on to the host. First send the host logon. Then send the user ID and password. */```

You can use block comments anywhere in a macro except in the middle of an identifier (such as a function or variable name) or inside a string constant. You can even nest comments in a block comment; the macro processor sorts out the pairs correctly.

Be careful when using block comments, however. If you fail to terminate the block comment correctly, the compiler will treat every statement in the rest of the macro as part of the block comment.

**Line Comments**

Use line comments when your comment text is brief. Line comments do not require a matching end-of-comment symbol.

There are two types of line comments:

- Double hyphens (--) 
- Semicolon (;)

**Note:** Use double hyphens for your line comments because the semicolon has special meaning for some of the CASL elements, such as the print statement. The semicolon comment indicator is supported only for backward compatibility.
Double Hyphens  When you use the double-hyphen indicator, any characters that follow the hyphens, through the end of the line, are considered comment text. Since double hyphens are used only to designate a comment, you can use them anywhere (except in the middle of identifiers or string constants).

The following is an example of a double-hyphen comment:

```
-- Macro name: HELLO.XWS
-- Date: 12-18-2000
```

Semicolon  Use the semicolon indicator only in a location where you would normally place a CASL statement, as shown in the following examples:

```
print "Hi," ; This is a comment

reply userid
; Send your user ID to the host
```
Identifiers

Each variable, procedure, function, label, and other type of element used in a macro must have a unique name, referred to as an identifier.

An identifier can be any length up to 128 characters. The first character must be alphabetic or one of the following special characters: $, %, or _. The remaining characters can be alphabetic characters, special characters, or numbers; spaces cannot be used. Identifier names are not case-sensitive.

Unlike in some other programming languages (for example, BASIC), using the percent (%) or dollar ($) symbol in a variable name does not force the variable to be a particular data type. CASL determines the data type of a variable from the keyword used in its explicit declaration or from the type of expression assigned to it in an implicit declaration. Refer to Chapter 3, “Variables, Arrays, Procedures, and Functions,” for more information on variable declarations.

**Note:** Do not use the same identifier for different elements (for example, do not identify a variable with the same name assigned to a procedure). Duplicate identifiers are an error.
## Data Types

CASL supports the following data types:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>The integer data type represents positive and negative numbers. Internally, integers are stored as 32-bit signed integers, so values between -2,147,483,648 and 2,147,483,647 are possible.</td>
</tr>
<tr>
<td>Real</td>
<td>The real data type represents positive and negative floating point numbers. Internally, reals are stored as 4-byte IEEE floating point numbers, consisting of a sign bit, an 8-bit excess 127-bit binary exponent, and a 23-bit mantissa. The range of possible values is approximately 3.4E-38 to 3.4E+38.</td>
</tr>
<tr>
<td>String</td>
<td>The string data type represents variable length strings. A null string has zero length. The maximum length of any string is 32,767 characters. A string variable has a particular length at any given time, but the length can change when a new value is assigned to the variable. The new length can be longer or shorter than the original length of the string.</td>
</tr>
<tr>
<td>Boolean</td>
<td>The Boolean data type represents true or false values.</td>
</tr>
<tr>
<td>Byte</td>
<td>The byte data type consists of unsigned, non-fractional values of 0 (zero) to 255. It is often preferable to use bytes, rather than integers, in arrays because bytes require less memory than integers.</td>
</tr>
<tr>
<td>Word</td>
<td>The word data type consists of unsigned, non-fractional values from 0 (zero) to 65,535. As with the byte data type, you may find it preferable to set up your arrays using words, rather than integers.</td>
</tr>
<tr>
<td>Char</td>
<td>The char data type consists of a single-character string that can be assigned as strings or bytes.</td>
</tr>
<tr>
<td>Array</td>
<td>The array data type consists of multiple elements of a data type. You can have an array of integers, reals, strings, Booleans, bytes, words, or chars.</td>
</tr>
</tbody>
</table>

**Note:** For type-checking purposes, integer, byte, and word are all considered integers.
Chapter 2 Understanding the Basics of CASL

Constants

A CASL constant can be one of the following four types:

- Integer
- Real
- String
- Boolean

Integer Constants

Integer constants have one of the following formats:

- `[-] digit ...`  
  Decimal integers
- `[-] digit ... {h | H}`  
  Hexadecimal integers
- `[-] digit ... {o | O | q | Q}`  
  Octal integers
- `[-] digit ... {b | B}`  
  Binary integers
- `[-] digit ... {k | K}`  
  Kilo integers

Decimal Integers

Decimal integers use a base of 10, which means that 0 through 9 are valid digits. The following are examples of decimal integers:

1
-61

Hexadecimal Integers

Integer constants that end with an h or H are hexadecimal constants. These constants use a base of 16; therefore, the digits of the constant can be 0 through 9 and also a through f (lowercase or uppercase).

The first digit of a hexadecimal constant must always be numeric. If the leading digit is not numeric, you must supply a leading zero. The following are examples of hexadecimal constants:

0F0H
3f8h
Chapter 2 Understanding the Basics of CASL

Octal Integers

Integer constants that end with the letter o, O, q, or Q are octal constants. These constants use a base of 8, which means that 0 through 7 are valid digits. The following are examples:

17o
17Q

Binary Integers

Integer constants that end with a b or B are binary constants. Valid digits are 0 (zero) or 1 (one). Since the binary suffix b or B is also a valid hexadecimal digit, the macro processor treats a b or B in an integer constant as a binary suffix only if the b or B is not followed by a legitimate hexadecimal digit or by the hexadecimal character h or H.

The following is an example of a binary constant:

1001001B

Kilo Integers

Integer constants that end with a k or K are kilo integers. Valid digits for this type of integer constant are 0 (zero) through 9. When the macro processor encounters a k or K following an integer constant, it multiplies the constant by 1,024. For example, 32K becomes 32,768.

The following are examples of kilo integers:

64K
128k

Real Constants

Real constants specify a numeric value that may have a fractional component. For CASL to recognize a constant as a real constant, rather than as an integer constant, a decimal point (.) or the exponent indicator (e or E) must appear somewhere in it. A real constant must start with a digit (0 through 9) or a decimal point, optionally preceded by a minus sign.

Real constants have one of the following formats:

[-] [digit...] "." digit... [exponent]
[-] digit... exponent

The exponent has the following format:

{e | E} [+ | -] digit...
The following are examples of real constants:

0.2
-0.4e10
12.2e+10
20.3e-4

**String Constants**

String constants consist of a string of characters enclosed in single quotation marks ('') or double quotation marks (" "). You must use the same type of beginning and ending quotation marks. A null string is represented as " if you use single quotation marks or "" if you use double quotation marks.

The following is an example of a string constant:

'Statement'

In this example, the macro processor recognizes that Statement is a string is a string constant because it is enclosed in single quotation marks.

**Embedded Quotation Marks**

If you have a quotation embedded in a string constant, use the other type of quotation marks to enclose the embedded quotation, as shown in the following example:

'She said, "Hello."'

In this example, the quotation Hello is enclosed in double quotation marks because it is embedded in a longer string, which is enclosed in single quotation marks.

**Unprintable Characters**

To include an unprintable control character in a string constant, put a carat symbol before the control character (for example, ^G for the control-G). To specify a numeric string, enclose the string in angle brackets (for example, <007> for the ASCII value 7). The following table lists the control characters and their corresponding ASCII values.
### Chapter 2 Understanding the Basics of CASL

**ASCII Control Codes**  
The following table lists ASCII control codes and corresponding control values.

<table>
<thead>
<tr>
<th>ASCII</th>
<th>Control+Character</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>^@</td>
<td>NUL</td>
<td>Null</td>
</tr>
<tr>
<td>1</td>
<td>^A</td>
<td>SOH</td>
<td>Start of header</td>
</tr>
<tr>
<td>2</td>
<td>^B</td>
<td>STX</td>
<td>Start of text</td>
</tr>
<tr>
<td>3</td>
<td>^C</td>
<td>ETX</td>
<td>End of text</td>
</tr>
<tr>
<td>4</td>
<td>^D</td>
<td>EOT</td>
<td>End of transmission</td>
</tr>
<tr>
<td>5</td>
<td>^E</td>
<td>ENQ</td>
<td>Enquiry</td>
</tr>
<tr>
<td>6</td>
<td>^F</td>
<td>ACK</td>
<td>Positive acknowledgment</td>
</tr>
<tr>
<td>7</td>
<td>^G</td>
<td>BEL</td>
<td>Bell</td>
</tr>
<tr>
<td>8</td>
<td>^H</td>
<td>BS</td>
<td>Backspace</td>
</tr>
<tr>
<td>9</td>
<td>^I</td>
<td>HT</td>
<td>Horizontal tab</td>
</tr>
<tr>
<td>10</td>
<td>^J</td>
<td>LF</td>
<td>Line feed</td>
</tr>
<tr>
<td>11</td>
<td>^K</td>
<td>VT</td>
<td>Vertical tab</td>
</tr>
<tr>
<td>12</td>
<td>^L</td>
<td>FF</td>
<td>Form feed</td>
</tr>
<tr>
<td>13</td>
<td>^M</td>
<td>CR</td>
<td>Carriage return</td>
</tr>
<tr>
<td>14</td>
<td>^N</td>
<td>SO</td>
<td>Shift out</td>
</tr>
<tr>
<td>15</td>
<td>^O</td>
<td>SI</td>
<td>Shift in</td>
</tr>
<tr>
<td>16</td>
<td>^P</td>
<td>DLE</td>
<td>Data link escape</td>

<tr>
<td>18</td>
<td>^R</td>
<td>DC2</td>
<td>Device control 2</td>
</tr>
<tr>
<td>19</td>
<td>^S</td>
<td>DC3</td>
<td>Device control 3</td>
</tr>
<tr>
<td>20</td>
<td>^T</td>
<td>DC4</td>
<td>Device control 4</td>
</tr>
<tr>
<td>21</td>
<td>^U</td>
<td>NAK</td>
<td>Negative acknowledgment</td>
</tr>
<tr>
<td>22</td>
<td>^V</td>
<td>SYN</td>
<td>Synchronous idle</td>
</tr>
<tr>
<td>23</td>
<td>^W</td>
<td>ETB</td>
<td>End of transmission block</td>
</tr>
<tr>
<td>24</td>
<td>^X</td>
<td>CAN</td>
<td>Cancel</td>
</tr>
<tr>
<td>25</td>
<td>^Y</td>
<td>EM</td>
<td>End of medium</td>
</tr>
<tr>
<td>26</td>
<td>^Z</td>
<td>SUB</td>
<td>Substitute</td>
</tr>
</tbody>
</table>
Chapter 2 Understanding the Basics of CASL

To send a control code, use the Control+Character value or the name listed in the preceding table. If you use the name, be sure to enclose it in angle brackets. For example, you can use ^[ or <ESC> to represent the ASCII code for Escape. The macro processor interprets this as the Escape code 1B hexadecimal.

To send the code as a string, precede it with a grave accent (`).

<table>
<thead>
<tr>
<th>ASCII</th>
<th>Control+Character</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>27</td>
<td>^[</td>
<td>ESC</td>
<td>Escape</td>
</tr>
<tr>
<td>28</td>
<td>^\</td>
<td>FS</td>
<td>File separator</td>
</tr>
<tr>
<td>29</td>
<td>^]</td>
<td>GS</td>
<td>Group separator</td>
</tr>
<tr>
<td>30</td>
<td>^^</td>
<td>RS</td>
<td>Record separator</td>
</tr>
<tr>
<td>31</td>
<td>^_</td>
<td>US</td>
<td>Unit separator</td>
</tr>
</tbody>
</table>

Special Characters

Some characters have special meanings to Accessory Manager's CASL processor. If you want a special character to be recognized as part of a string constant, precede the character with a grave accent.

This is illustrated in the following examples:

- reply "|"
- reply "\|"

In the first example, the macro processor interprets the "|" as a carriage return. In the second example, the macro processor interprets "\|" as the vertical bar character.
The special characters are as follows:

<table>
<thead>
<tr>
<th>Character</th>
<th>Special Meaning to the CASL Processor</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;</td>
<td>Double quotation mark. Delimiter around a string constant.</td>
</tr>
<tr>
<td>'</td>
<td>Single quotation mark. Delimiter around a string constant.</td>
</tr>
<tr>
<td>\</td>
<td>Backslash. Precedes an ASCII value.</td>
</tr>
<tr>
<td></td>
<td>Vertical bar. A carriage return.</td>
</tr>
<tr>
<td>`</td>
<td>Grave accent. Marks special characters in a string.</td>
</tr>
<tr>
<td>^</td>
<td>Caret. Precedes another character to denote an ASCII control character, as in ^A for start of header control character.</td>
</tr>
<tr>
<td>&lt;</td>
<td>Less-than symbol. Used to mark the beginning of a keystroke name.</td>
</tr>
</tbody>
</table>

If you want a grave accent to be recognized as part of the string, precede it with another grave accent. The first one protects the second.

Using the grave accent with these special characters is essential when using the wait statement to wait for a string that contains these characters. Refer to “wait (statement)” on page 344.

When working with a block mode terminal emulator, such as T 27 or UTS, you often need to use the grave accent in a press or reply statement that includes control characters. Refer to “press (statement)” on page 281 and “reply (statement)” on page 297.

Keystroke Names

If you need to specify a key on the PC keyboard or a terminal emulation keystroke in a string constant, enter it as follows:

""<Transmit>""
Chapter 2 Understanding the Basics of CASL

String Constants That Continue on a New Line

When you have a string constant that is too long to fit on one line, break the string into segments, enclosing each segment with quotation marks, and use the string concatenation symbol (+) to join the segments. Do not use the line continuation sequence (...) or a carriage return inside the quotation marks. The following example shows how to continue a string constant on a new line:

```plaintext
message "You are running a new system " + ...
 "software version"
```

Boolean Constants

A Boolean constant is one of the following:

```plaintext
defalse
deftrue
```
Expressions

CASL expressions include arithmetic, string, relational, and Boolean expressions. There is a specific order of evaluation applied to these expressions based on precedence and the use of parentheses. A type conversion can be performed for some expressions. When a type conversion is performed, the original type of the expression is converted to a different type. Type conversion is explained later in this chapter.

Operators perform mathematical, logical, and string operations on expressions, or arguments. Most of the CASL operators have two arguments in the following format:

```
argument1 operator argument2
```

Argument1 and argument2 must be expressions of the valid type for the operator involved. In general, you can use any expression containing a syntactically correct mixture of arguments and operators in a macro wherever the result is allowed. For example, the following statements are functionally equivalent:

```
wait 9 seconds
wait 4 + 5 seconds
wait 3 * 3 seconds
wait 18 / 2 seconds
```
Expressions are normally evaluated based on the precedence of the operators; higher precedence operators are applied before lower precedence operators. You can control the order of evaluation of any expression by using parentheses. Sub-expressions inside parentheses are evaluated before the main expression.

The general precedence of operators is as follows:

- Highest—Arithmetic and string operators
- Next highest—Relational operators
- Lowest—Boolean operators

Arithmetic and string operators share the same precedence level because they cannot be mixed. Arithmetic and string expressions are completely evaluated before participating in relational expressions. Relational expressions are completely evaluated before participating in Boolean expressions.

Within a particular type of expression, the precedence rules for that type are followed.
Arithmetic Expressions

You build arithmetic expressions using numeric arguments and arithmetic operators. Unary operators are evaluated from right to left, and binary operators of the same precedence are evaluated from left to right.

The standard arithmetic operators you can use are listed in groups of decreasing precedence. Each operator has a symbolic representation and a name.

The operators with the highest precedence are as follows:

- BitNot
- Negate

The operators with the second highest precedence are as follows:

rol Rol
ror Ror
shl Shl
shr Shr

The operators with the third highest precedence are as follows:

& BitAnd
^ BitXor
/ Division
\ IntDivision
mod Modulo
* Multiplication
Chapter 2 Understanding the Basics ofCASL

The operators with the lowest precedence are as follows:

+ Addition
| BitOr
- Subtraction

These operators, which are listed in alphabetical order, are explained in the paragraphs that follow.

Addition produces the numeric sum of its arguments. The following is an example:

2 + 2

BitAnd, BitOr, BitXor, and BitNot are bitwise operators. They are common operators in the assembler language. In the following diagrams, which show how these operators work, x and y are bit arguments and z is the result of the bitwise operation.

<table>
<thead>
<tr>
<th>BitAnd</th>
<th>BitOr</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>y</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>BitXor</th>
<th>BitNot</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>y</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>x</th>
<th>z</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>
The following examples use BitAnd, BitOr, BitXor, and BitNot, in that order:

\[
\begin{align*}
\text{somevar} & = \text{bitvar1} \& \text{bitvar2} \\
\text{somevar} & = \text{somevar} \mid \text{bitvar3} \\
\text{somevar} & = \text{somevar} ^{\sim} \text{bitvar3} \\
\text{somevar} & = -\text{bitvar1}
\end{align*}
\]

Division and IntDivision cause the mathematical division of the first argument by the second argument. For Division, the result is a real (floating point) value if either of the two quantities is a real; for IntDivision, only integers are allowed, and the result is an integer, possibly truncated. The following are examples:

\[
\begin{align*}
x & = 3.0 / 2.0 \quad \text{The result is 1.5} \\
\text{an_integer} & = 3 \mod 2 \quad \text{The result is 1}
\end{align*}
\]

Modulo returns the remainder after dividing its first argument by its second argument, as shown in the following example:

\[
10 \mod 4 \quad \text{The result is 2}
\]

Multiplication is an algebraic operator that returns the product of two arguments. The following is an example:

\[
2 \ast 2
\]

Negate is also called unary minus in some programming languages. It multiplies a numeric value by minus one. The Negate operator is used in the following example:

\[
\text{neg_num} = -\text{pos_num}
\]

Rol, Ror, Shl, and Shr are bitwise operators that either rotate or shift the bits in an individual 8-bit, 16-bit, or 32-bit argument.

When you use these operators, the first argument has its value moved the number of positions specified in the second argument. In rotation, the bits that are moved off one end of the first argument are moved back onto the other end of the argument. In shifting, the bits that are moved off the end of the argument are discarded and replaced with zeros on the other end of the argument.

The Rol and Shl operators move bits to the left (toward the most significant bit) while the Ror and Shr operators move bits to the right (toward the least significant bit). The following are examples of these operators:
print 1 ror 8
print 1 shr 8
print 1 rol 8
print 1 shl 8

For the first example, '16,777,216' is printed. For the second example, '0' (zero) is printed. For the third and fourth examples, '256' is printed.

Subtraction reduces the first argument by the value in the second argument. Both arguments must be numeric. The following is an example:

4 - 2
Chapter 2 Understanding the Basics of CASL

String Expressions

There is only one string operator—the string concatenation operator. However, CASL provides a comprehensive set of statements and functions that you can use to perform other string operations.

String Concatenation Operation

String concatenation joins two strings. The string concatenation operator is a plus sign (+).

When you use the string concatenation operator, two strings connected by a plus sign (+) are joined together to make one long string. This is shown in the following example:

"123" + "456" is the string "123456"

For a complete list and description of the statements and functions that perform string operations, refer to Chapter 5, “Functional Purpose of CASL Elements,” and Chapter 6, “CASL Language.”
Relational Expressions

Relational expressions result in Boolean values. The relational operators have no precedence.

You can use the following relational operators to compare numbers, strings, or Booleans:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>Equal</td>
</tr>
<tr>
<td>&gt;=</td>
<td>GreaterOrEqual</td>
</tr>
<tr>
<td>&gt;</td>
<td>GreaterThan</td>
</tr>
<tr>
<td>&lt;&gt;</td>
<td>Inequality</td>
</tr>
<tr>
<td>&lt;=</td>
<td>LessOrEqual</td>
</tr>
<tr>
<td>&lt;</td>
<td>LessThan</td>
</tr>
</tbody>
</table>

*Equality* compares two expressions (either numeric or string) and returns *true* if the two items compared are exactly the same. Trailing spaces are significant in string comparisons. The following are examples of the *Equality* operation:

```plaintext
if a_variable = 2 then statement
```

**Note:** The equal sign is also used for variable assignment, as shown in the following example where the variable `a_variable` is assigned a value of 2:

```plaintext
a_variable = 2
```

*GreaterOrEqual*, *GreaterThan*, *LessOrEqual*, *LessThan*, and *Inequality* are also comparison operators. They apply to numeric quantities or strings. While the comparison of numeric quantities is straightforward, the comparison of strings is more complex.

In string comparisons, single characters are compared on the basis of their ASCII collating sequence; therefore, "Z" is less than "a." For longer strings, characters are compared position by position until a character is found that is different; then the characters that are different are compared on the basis of their ASCII collating sequence.
Chapter 2 Understanding the Basics of CASL

The following examples show the LessThan, LessOrEqual, GreaterThan, and GreaterOrEqual operators:

if some_var < 2 then statement

if string1 <= string2 then statement

while length(a_string) > 12

statement until rec_pointer => max_records
Chapter 2 Understanding the Basics of CASL

Boolean Expressions

The Boolean operators you can use are listed in the order of decreasing precedence.

The operator with the highest precedence is \texttt{not}. The operator with the next highest precedence is \texttt{and}. The operator with the lowest precedence is \texttt{or}.

The arguments to Boolean operators can be Boolean variables, relational expressions, or other Boolean expressions.

\texttt{And}, \texttt{Or}, and \texttt{Not} produce a true or false result from their arguments, that is, they see their arguments only as true or false, not as quantities. The \texttt{And} operator returns true only if both arguments are true. The \texttt{Or} operator returns true if either or both of its arguments are true. The \texttt{Not} operator returns the opposite of its argument.

The following examples contain these operators:

\begin{verbatim}
if null(a_string) and x = 1 then statement
if counter > maximum or inkey then statement
if not eof(fl) and inkey <> 27 then statement
flip = not flip
\end{verbatim}

If the value of the left argument of a logical operator is sufficient to determine the outcome of the expression, the right argument is not evaluated at all. This is the case when the left argument of the \texttt{And} operator is false, or when the left argument of the \texttt{Or} operator is true.

For instance, in the following example, the array reference
\begin{verbatim}
data[n]\end{verbatim}
will never attempt to index beyond the end of the array. If \(n\) were greater than 10, the expression \(n \leq 10\) would be false, and the right argument would never be evaluated.

\begin{verbatim}
integer data[10]
if n <= 10 and data[n] >= 0 then statement
\end{verbatim}
Chapter 2 Understanding the Basics of CASL

Type Conversion

You may find it is necessary to convert values from one type to another. CASL provides the means to perform a variety of type conversions. This section explains how to convert an integer to a string, a string to an integer, an integer to a hexadecimal string, and an ASCII value to its corresponding character string.

Converting an Integer to a String

To convert an integer to a string, use the `str` function. This function does not add leading or trailing spaces.

The following example illustrates how to use the `str` function:

```
reply str(share_to_buy)
```

In this example, `str` converts `share_to_buy` to a string, which is sent to the host with the `reply` statement.

Converting a String to an Integer

To convert a string to an integer, use the `intval` function. This function ignores leading spaces and evaluates the string until a non-numeric character is found.

You can convert a string to a decimal or hexadecimal integer. If you need a hexadecimal integer, add an H to the end of the string. If your hexadecimal string does not begin with a numeric character, place a 0 at the beginning of the string. If you need a kilo integer, add a K to the end of the string.

The following example illustrates how to use the `intval` function:

```
num = intval(user_input_string)
```

In this example, `intval` converts `user_input_string` to an integer and returns the result in `num`.

Converting an Integer to a Hexadecimal String

To convert an integer to a hexadecimal string, use the `hex` function. If the integer is below 65,536, the string is four characters long; otherwise, it is eight characters long.

The following example shows how to use this function:

```
print hex(32767)
```

In this example, the `hex` function converts the integer 32,767 to a hexadecimal string and displays the result on the screen.
**Converting an ASCII Value to a Character String**

To convert an ASCII value to its corresponding one-byte character string, use the `chr` function. The following is an example of how to use this function:

```python
cr = chr(13)
```

In this example, `chr` converts the ASCII value 13 to its corresponding carriage return character and returns the result in `cr`.

For more information on these and other CASL functions that perform type conversions, refer to Chapter 5, “Functional Purpose of CASL Elements,” and Chapter 6, “CASL Language.”
Compiler Directives

Compiler directives provide instructions for the macro compiler. CASL compiler directives let you do the following:

- Suppress label information
- Suppress line number information
- Trap an error
- Include an external file
- Define a macro description

**Suppressing Label Information**

By default, information about labels is included in the compiled version of your macro. To suppress the label information, add the `genlabels off` compiler directive at the beginning of your source macro. The default for this directive is `genlabels on`.

**Note:** If you use the `genlabels off` directive, you cannot use the `inscript` function or the `goto @ expression` statement in your macro.

**Suppressing Line Number Information**

Information about line numbers is also included as part of a compiled macro. To suppress this information, add the `genlines off` compiler directive at the beginning of your macro. The default for this directive is `genlines on`.

**Trapping an Error**

Use the `trap` compiler directive to enable and disable CASL’s error trapping feature. Error trapping is disabled (`trap off`) by default. To enable error trapping, set `trap on` just prior to a statement that might generate an error. For additional information about trapping and handling errors, refer to Chapter 4, “Interacting with the Host, Users, and Other Macros.”

**Note:** The `trap` compiler directive does not affect whether errors occur. It simply provides a way to effectively handle the errors if they do occur.
Chapter 2 Understanding the Basics of CASL

Including an External File

Use the `include` compiler directive when you want to include another file in the macro being compiled. The file is included in the macro following the `include` directive, as if the included file were part of the original file.

The `include` directive includes the file only once, no matter how many times you use the directive. The reason for this is that included files typically contain declarations, and including them more than once causes duplicate declaration errors.

Defining a Macro Description

Use the `scriptdesc` compiler directive to define descriptive text for a macro.

For more detailed information about these compiler directives, refer to Chapter 6, “CASL Language.”
Reserved Keywords

CASL reserves certain words called keywords. You may not use any of the keywords as identifier names. The reserved words are not case-sensitive.

Keywords include statements (such as `watch`), words that define time (such as `seconds` and `ticks`), and words that bind statements (such as `for` and `next`).

The following are the CASL keywords:

<table>
<thead>
<tr>
<th>abs</th>

In This Chapter

In a CASL macro, you use declarations to define your variables, arrays, procedures, and functions. Declarations make your macro more readable and maintainable; in some instances, they are mandatory.

This chapter contains information about declaring elements in the CASL language. It includes the following headings:

- Variables ................................................................. 64
- Explicit Variable Declarations ................................. 65
- Implicit Variable Declarations ................................ 67
- Arrays ........................................................................ 68
- Procedures ................................................................. 70
- Functions ................................................................. 73
- Scope Rules ............................................................... 75
- Calling DLL Functions .............................................. 77
Chapter 3 Variables, Arrays, Procedures, and Functions

Variables

A variable is a language element whose value can change during the course of running a macro. You use variables as storage areas where you can keep the results of a computation, data arriving from the host, and other data such as a user name or password.

With CASL, you can use two types of variables:

- Predefined variables (which you can reference in your macro)
- User-defined variables (which you define in your macro)

Predefined Variables

There are two types of predefined variables:

- System variables
- Module variables

System variables contain user-profile (or configuration) information or session information. The variables that contain session information are stored in a session profile. Each session entry contains session parameters such as the terminal emulation type, user ID, and password.

Module variables contain tool-specific information and are stored in a session profile. For example, if a session uses the INFOConnect connection tool, the entry contains settings for INFOConnect paths and so on. To reference these variables, use the assume statement as follows:

```
assume device "ICSTOOL"
```

User-Defined Variables

User-defined variables are those you define in your macro. These variables can be local to one macro or shared across multiple macros.
Explicit Variable Declarations

Explicitly declare your variables to make your macro more readable and maintainable.

Explicit declarations consist of a data-type identifier and a variable name. You can use any variable name you like as long as it is not the same as that of another language element in your macro. It is often helpful to assign a name that reflects the variable's purpose; for example, the name file_name is more descriptive than the name xyz.

Your variable names can contain any combination of alphanumeric characters as well as some symbols. The first character must be alphabetic, or one of these special characters: $, %, or _. Variable names can consist of up to 32,767 characters.

The following illustrates the general form of explicit declaration:

data_type name [, name]...

**Single-Variable Declarations**

You can declare variables one to a line. The following is an example of single declaration:

integer counter

In this example, counter is declared as an integer variable.

**Multiple-Variable Declarations**

You can also declare more than one variable on a logical line, but the variables must be of the same type. Multiple declaration is shown in the following example:

integer row, col

In this example, both row and col are declared as integer variables.
Chapter 3 Variables, Arrays, Procedures, and Functions

The following are examples of explicit declarations for other data types:

boolean failed
real percentage
string file_name, extension

Initializers

Variables you declare explicitly are automatically initialized by the compiler: strings are initialized to nulls; reals and integers are initialized to zero. To initialize these variables to a different value, use the assignment operator (=).

The following are examples of variable initialization:

    a_var = 10
    amount = "Quantity"

In the first example, the integer variable a_var is initialized to 10. In the second example, the string variable amount is initialized to Quantity.

Public and External Variables

If you want to share a variable among multiple macros, declare the variable as public in the main macro (parent macro) and as external in the other macros (child macros). The data type of the variables must match. If the variable is an array, the declared array size must match. As with any other explicit declaration, you can declare multiple public or external variables of the same type on one logical line, separating the variable names with commas.

The following are examples of public and external variables:

    public integer user_name    (parent macro declaration)
    external integer user_name  (child macro declaration)

For additional information about public and external variables, refer to Chapter 4, “Interacting with the Host, Users, and Other Macros.”
Implicit Variable Declarations

You can implicitly declare a variable if the first time it is used it is possible to infer its type from the context. However, use implicit declarations sparingly, for your macro is less readable and maintainable when variables are not declared explicitly.

The most common case of implicit declaration is where the variable is assigned a value. In this case, the type of the variable is implicitly declared to match the type of the expression assigned to it. In the following example, `user_name` is implicitly declared as a string variable because the string "John" is assigned to it. "John" is enclosed in quotation marks; you must use quotation marks to enclose a data string assigned to a string variable.

```
user_name = "John"
```

The same concept applies for all other cases where the variable type can be inferred. For instance, the following example implicitly declares `count` to be an integer variable because the initial value is an integer.

```
for count = 1 to 10
    ...
    ...
next
```
Arrays

Arrays require an explicit declaration; it is not possible to implicitly declare an array.

An array declaration is similar to other declarations, but you must also declare the dimensions. Enclose the dimensions of the array in square brackets.

**Note:** The elements in CASL arrays are numbered starting from zero; therefore, there are actually \( n + 1 \) elements in an array of size \( n \).

**Single-Dimensional Arrays**

Some arrays have only one dimension. For example, you declare a single-dimension array of 30 integers as follows:

```casl
integer epsilon[29]
```

In this example, the size of the array `epsilon` is 29, but there are actually 30 elements in the array because the first element is element 0 (zero).

**Multidimensional Arrays**

Arrays can also be multidimensional. You declare multiple dimensions by providing multiple dimension sizes, separated by commas. For example, you declare a 10-by-20 string matrix in the following way:

```casl
string matrix[9, 19]
```
You can use alternative bounds declarations when you need to use bounds other than the default. The following examples show how to declare arrays with alternative bounds:

```
integer vector[0:99]
integer profile[3:6]
integer samples[-10:10]
```

The first example, an array of 100 elements, is equivalent to

```
integer vector[99]
```

because 0 is the default lower bound. In the second example, the array `profile`, an array of 4 elements, is indexed from 3 to 6. The array `samples`, an array of 21 elements, is indexed from -10 to 10 in the third example.

When you declare multiple dimensions, you can use alternative bounds declarations for each dimension individually. For example, declare a matrix whose first dimension is indexed from 10 to 30 and whose second dimension contains 100 integers in the following way:

```
integer data[10:30, 99]
```
Chapter 3 Variables, Arrays, Procedures, and Functions

Procedures

A procedures definition is a declaration because it only defines the statements that make up the procedure. The statements themselves are not executed until the procedure is called.

You must declare a procedure before you use it. A procedure cannot be inside a function or another procedure.

Procedures are useful for replacing groups of statements that are frequently used. For example, a macro that repeatedly performs a complicated sequence of steps can use one common procedure to perform the task. The statement(s) that call the procedure simply pass the appropriate information to the procedure, and it performs the task. If you need to return a result, consider using a function instead of a procedure.

The following example illustrates the syntax of a procedure definition:

```
proc name [takes arglist]
    ...
    ...
endproc
```

Procedure Argument Lists

As shown in the preceding syntax illustration, a procedure can have an argument list. The arglist is optional, and is used only if the procedure takes arguments. If arguments are included, you must use the same number and type of arguments in both the procedure and the statement that calls the procedure. The arguments are assumed to be strings unless otherwise specified.

The syntax of arglist is as follows:

```
[type] <argument [, [type] argument]...```
The following is an example of a procedure definition:

```c
/*
 * This procedure sends the user ID and password to the
 * host.
 */
proc logon takes username, passwrd
    reply username
    wait 2 seconds
    reply passwrd
endproc
```

In this example, the statements enclosed in the /* and */ symbols are comments describing the procedure's purpose. The procedure, which is named `logon`, expects two string arguments—`username` and `password—and it sends the arguments to the host. When the procedure ends (endproc), control is passed to the statement immediately following the one that called the procedure.

You call this procedure as follows:

```c
logon userid, password
```

The arguments `userid` and `password` are passed to the procedure `logon`.

---

**Forward Declarations for Procedures**

You can use forward declarations to declare procedures whose definitions occur later in the macro. The syntax of a forward procedure declaration is the same as the first line of a procedure definition, with the addition of the `forward` keyword.

Forward declarations are useful if you want to place your procedures near the end of your macro. A procedure must be declared before you can call it; the forward declaration provides the means to declare a procedure and later define what the procedure is to perform.

The following syntax is used for a forward declaration:

```c
proc name [takes arglist] forward
```

When the procedure definition is encountered, each of its arguments (if provided) must match the data type of the corresponding argument in the forward declaration.
Chapter 3 Variables, Arrays, Procedures, and Functions

The following example shows how to set up the logon procedure using a forward declaration:

```casl
proc logon takes ... -- The forward declaration
    username, passwd forward
logon userid, password -- The procedure call
```

```casl
proc logon takes username, passwd -- The procedure
    reply username
    wait 2 seconds
    reply passwd
endproc
```

You can also use the perform statement to call a procedure before it is declared. This is shown in the following example:

```casl
perform logon userid, password
```

External Procedures

Procedures can be an integral part of a macro, or they can be in separate files. The latter allows you to keep a library of procedures you often use; you don’t have to duplicate the procedure for each macro you create.

To include an external procedure in a macro, use the include compiler directive. For example, suppose the logon procedure, which was described previously, is an external procedure that is stored in a file called MYPROCS.XWS. To include it in your macro, add the following line at the beginning of the macro:

```casl
include "myprocs"
```

For more information about the proc...endproc procedure construct, the perform statement, and the include compiler directive, refer to Chapter 6, “CASL Language.”
Functions

A function is similar to a procedure, but it returns a value. You must declare the type of the return value within the function definition and specify a return value before returning.

You must declare a function before you can use it. A function cannot be inside a procedure or another function.

The syntax of a function definition is as follows:

```
func name [(arglist)] returns type
  ...
  ...
endfunc
```

### Function Argument Lists

As for a procedure, the arglist is optional. The syntax of the arglist is the same as for procedure arguments.

The following example illustrates a function with an arglist:

```
func calc(integer x, integer y) returns integer
  if x < y then return x else return y
endfunc
```

In this example, the integers x and y are the function arguments. The values of x and y are passed to the function when it is called. The function returns one or the other value depending on the outcome of the if...then...else comparison. If x is less than y, x is the return value; if x is not less than y, the value of y is returned.

You call this function as follows:

```
integer return_value

return_value = calc(3, 8)
```

The integer values of 3 and 8 are passed to the function calc where they are used as the values x and y in the function. The function returns the result of its calculations in the variable return_value.
Forward Declarations for Functions

You can use forward declarations to declare functions whose definition occurs later in the macro. The syntax of a forward function declaration is the same as the first line of a function definition, with the addition of the forward keyword.

Forward declarations are useful if you want to place your functions near the end of your macro. A function must be declared before you can call it. The forward declaration provides the means to declare a function and later define what the function is to do. The following syntax is used for a forward declaration:

```
func name [(arglist)] returns type ...
  forward
```

When the function definition is encountered, each of its arguments (if provided) must match the data type of the corresponding argument in the forward declaration.

The following shows how to set up the `calc` function using a forward declaration:

```
integer return_value -- The integer declaration

func calc(integer x, integer y) ... -- The forward
  returns integer forward -- declaration

return_value = calc(3,8) -- The function call

func calc(integer x, integer y) ... -- The function
  returns integer
    if x < y then return x else return y
endfunc
```

External Functions

As with procedures, functions can be in separate files. To include an external function in a macro, use the `include` compiler directive. For example, if the `calc` function is external to the macro and is stored in a file called MYPROCS.XWS, add the following line at the beginning of the macro to include it in the macro:

```
include "myprocs"
```

For more information about the `func...endfunc` function and the `include` compiler directive, refer to Chapter 6, "CASL Language."
Scope Rules

You can reference a variable from the line on which it is declared until the end of its scope. This is true for both implicit and explicit declarations.

Local Variables

The variables you declare inside procedures and functions are local variables. The scope of local variables terminates when the function or procedure that defines them ends. You can refer to and modify these variables only while the procedure or function is executing. Their values are lost when the procedure or function returns control.

Global Variables

The variables you declare outside procedures and functions are global variables. The scope of global variables terminates when the macro ends. You can refer to and modify these variables within and outside procedures and functions. They retain their values throughout execution of the macro.

Default Variable Initialization Values

The local and global variables you declare are initialized to default values when they are created. The default value for each data type is as follows:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>0</td>
</tr>
<tr>
<td>Real</td>
<td>0.0</td>
</tr>
<tr>
<td>String</td>
<td>&quot;&quot; (the null string)</td>
</tr>
<tr>
<td>Boolean</td>
<td>False</td>
</tr>
<tr>
<td>Array</td>
<td>Each element is initialized to the array-type default.</td>
</tr>
</tbody>
</table>

Local variables are initialized each time the procedure or function begins execution. Global variables are initialized once when the macro begins execution.

Procedure and function arguments are like local variables, but they are not initialized to default values like other local variables. They receive their values from the actual arguments.
Chapter 3  Variables, Arrays, Procedures, and Functions

Labels

The scope of labels you declare inside procedures and functions terminates when the function or procedure that defines them ends. You can refer to these labels only while the procedure or function is executing, and only from within the procedure or function.

The scope of labels you declare outside procedures and functions terminates when the macro ends. Procedures and functions cannot reference labels that are not defined within the procedure or function.
Calling DLL Functions

In a CASL macro, you can call functions located in external libraries. These libraries are referred to as Dynamic Link Libraries (DLLs) in the Windows environment. This provides access to Windows' kernel, user, or GDI functions, third-party libraries, and in-house libraries. The advantage of using external libraries is to provide capabilities not found in CASL and to improve the efficiency of critical routines.

An external library is a collection of functions that exist in a separate file. That file is loaded by the operating system only when a program (or macro in our case) calls one of the functions contained in it. This reduces the size of programs, since many programs can call the same library, and allows new functionality to be added to CASL.

Note: The following information is intended for experienced Windows programmers.

Declaring DLL Functions

The functions in your CASL macro that call DLL functions are declared in a manner similar to CASL forward declarations. Once declared, the functions can be used exactly like other functions in your macro. Use the following syntax to declare the functions:

Function with a return value:

```
func name [(arglist)] returns type ...
    library filename [name (string)]
```

Procedure without a return value:

```
proc name [takes arglist ] library filename ... 
    [name (string)]
```

The name can be the real name of the function or a name preferred by the user. In the latter case, the optional name parameter at the end of the declaration must provide the real function name.

The following examples illustrate library declarations:

```
func IsCharAlpha(char x) returns boolean ...
    library "user.exe"
```
USER.EXE is one of the DLLs that comprise the Windows core.

```c
func myFunc(integer x, real y) returns integer ...
   library "mylib.dll" name "FredFunc"
```

```c
func countLetters(string x) returns integer ...
   library "stringlib.dll"
```

```c
proc do_something takes integer x, byte y, string z ...
   library "something.dll"
```

**Note:** Since the functions are only declared in the macro, the parameter names used in the declarations (x, y, and z) are place holders and can be any valid variable name. Make sure you include the file name extension .DLL. Also, a path is required if the DLL is not located in any directory that is searched automatically by Windows.

**Parameter and Return Values**

The following CASL data types can be passed as parameters to DLL functions: integer, real, string, boolean, byte, and word.

The list is the same for return values with the exception of real, which is not returned.

A DLL function is written in a language such as C/C++. You need to match the CASL data type to the data type expected by the function being called.
Use the following table to select the data type you need.

<table>
<thead>
<tr>
<th>CorC++ Data Type</th>
<th>CASL's Corresponding Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>long (32 bit data)</td>
<td>integer</td>
</tr>
<tr>
<td>unsigned long</td>
<td>integer</td>
</tr>
<tr>
<td>int (16 bit data)</td>
<td>word</td>
</tr>
<tr>
<td>short</td>
<td>word</td>
</tr>
<tr>
<td>unsigned int or short</td>
<td>word</td>
</tr>
<tr>
<td>char (numeric value)</td>
<td>\word</td>
</tr>
<tr>
<td>char (single letter)</td>
<td>char</td>

</table>

CASL integers are 32-bit signed values, CASL words and bytes are 16- and 8-bit unsigned values respectively. Keep this in mind when assigning values to variables. Where a function takes or returns an 8- or 16-bit value that is designated as true or false, you can define it as Boolean and use the true or false keywords built into CASL.

**Note:** CASL does not pass the string itself to a function. Instead the location (address) of the string is passed. In C, this is referred to as a pointer. In CASL, you simply use a string variable as a parameter or place the desired text in quotes. CASL handles the job of passing the correct information.

Sometimes functions use the pointer as a method of returning data over and above the return value. Since the function has the location of the string, it can write data to that location. For example, a function that converts text to uppercase might simply do the job “in place,” so that the string you passed as a parameter is also the string that contains the uppercase text. In this case, a string variable must be used so that you can reference the string later.
You need to make sure that data returned in the string does not exceed the length of the original string. For example, you may have a function named path that takes the name of a file as a parameter and returns, in the same string, the full path specification for that file, as follows:

```c
string file_str
file_str = "myfile.txt"
path (file_str)
```

In this case, you will get a truncated path name if it is longer than the string. The function assumes it has enough space and will write beyond the end of your original string. This can corrupt your data or lock up your computer. The following macro shows the correct approach, making the string long enough to accommodate the longest string anticipated (in the case of DOS path names, 128 characters).

```c
string file_str
file_str = "myfile.txt"  // Add extra blanks
path (file_str)
strip (file_str, " ", 1)  // Remove excess blanks
```

### Non-Supported Parameters and Return Values

Functions written in languages such as C can accept a wide range of parameters not supported by CASL DLL calls, such as arrays and structures. If you want to access such functions (for example, in third-party libraries), you must write intermediate libraries that translate the data being passed or returned.

### Writing Windows DLLs

Before you write DLLs, you should have experience with a language such as C and have access to a compiler that supports Windows programming.
To access functions in a DLL, a DEF file must export each of the callable functions in its EXPORTS section. If you are not already familiar with writing DLLs, you should refer to the books available that provide detailed explanations of how to program Windows applications and DLLs.

**Note:** For string handling, remember that you are only returning the address of the string. This means that the address must remain valid after the function ends. Do not return a local string (one on the stack). Declare any string to be returned as static or allocate it from heap memory. However, if any memory is allocated on the heap, whether for strings or for any other data, it must be freed at some point before the macro terminates. Therefore, you must free the memory from the function that allocates it or provide another function to free it.

As you write DLLs to interface to Windows, you might need access to Accessory Manager parent and child (session) window handles. To access these handles, declare the following at the top of the macro:

```c
/*Handle to Accessory Manager parent window */
systemvar integer _hWndFrame

/* Handle to script's child window */
sessionvar integer _hWndSession
```

After the declaration, _hWndSession and _hWndFrame are used in the same manner as system and session variables.
In This Chapter

This chapter includes the following headings:

- Interacting with the Host ........................................ 84
- Communicating with a User .................................. 87
- Invoking Other Macros ........................................ 90
- Exchanging Variables ......................................... 91
- Trapping and Handling Errors .............................. 92
Interacting with the Host

CASL provides a number of language elements you can use to interact with a host. For example, the \texttt{wait} statement provides basic data-handling functions, while the \texttt{watch} statement offers more sophisticated methods for handling data.

**Waiting for a Character String**

Use the \texttt{wait} statement when you need to wait for a specific, unique string of text, as in the following example:

```
wait for "What is your first name?"
```

Note that the string "What is your first name?" is enclosed in quotation marks because it is a string constant.

The \texttt{wait} statement does not require a complete sentence as shown in the previous example. If just the word "name?" is unique at the time the macro executes the \texttt{wait} statement, you can shorten the statement as follows:

```
wait for "name?"
```

You can have your \texttt{wait} statement wait for one of several conditions to occur. For example, if you want to send a carriage return when your macro receives either "more" or "press enter" from the host, write the statement as follows:

```
wait for "more", "press enter" : reply
```

The default wait time for the \texttt{wait} statement is forever. You can specify a specific time period for the macro to wait, as shown in the following example.

```
reply -- Send CR
wait 2 seconds for "login:" -- Wait
if timeout then{
    alert "Host not responding", ok
end
}
```

In this example, the macro waits two seconds for the host to send the login: prompt. If a timeout occurs before the prompt appears, the user is alerted and the macro ends.
By default, the `wait` statement is not case- or space-sensitive. If
your macro requires an exact match, you must use the statement’s
case or space modifiers (or both). There are several other
conditions for which a `wait` statement can wait, including waiting
to receive a specific count of characters and waiting for the
connection to be quiet. For a complete list of `wait` conditions, refer
to “`wait` (statement)” on page 344.

Use the `watch...endwatch` construct when you need to wait for
any one of several conditions to occur and then take an action
based on that condition, as shown in the following example:

```
watch for
    key 27, "$"       : end
    "more:"         : wait 1 second : reply
endwatch
```

In this example, when the `watch` statement is encountered, the
macro pauses while waiting for one of the two conditions to take
place. The statement, or statements, to the right of the colon are
executed for whichever condition occurs first.

Note that `watch...endwatch` is not a looping construct. If you
want to repeat the `watch...endwatch` statements, enclose them in
a `while...wend` or a `repeat...until` construct. The following
example shows the `while...wend` construct:

```
while online
    watch for
        key 27, "$"       : end
        "more:"         : wait 1 second : reply
    endwatch
wend
```

This example is taken from a simple macro that automates
reading electronic mail on a host. The `while...wend` loop is
needed because the `more:` prompt will appear multiple times
during the reading process.

As specified by the first line of the `watch` construct in the previous
example, the macro ends if the user presses Esc (key 27). If `more:
is found, the macro waits one second and then uses the `reply`
statement to send a carriage return to the host. If the dollar sign
($) appears, there is no more mail to read, and the macro ends.
Like the wait statement, the watch statement can watch for several different kinds of conditions. For a complete list of the conditions, refer to “watch...endwatch (statements)” on page 348.

Setting and Testing Time Limits

Use the timeout system variable to determine if the condition for which you are waiting or watching has occurred within an expected time frame. To use the timeout system variable, you must set a timeout value for the wait or watch condition. Then you can test the timeout system variable; it returns true if the condition was not satisfied or false if it was satisfied.

For example, sometimes a user has to press Enter a number of times before the host recognizes the response. You can set up a simple routine to handle this situation:

```
repeat
  reply
  wait 1 second for "Login:"
until not timeout
reply userid
end
```

This example shows how to use the repeat...until construct to execute the same statements one or more times. When the repeat...until condition is satisfied, macro execution continues with the statement following the repeat...until construct.

In the example, the macro uses the reply statement without an argument to send only a carriage return character to the host. Then it waits one second for the string "Login:" to arrive. If the string does not arrive within the one-second time frame (timeout is true), the macro repeats the statements in the repeat...until construct. If the string arrives within the time frame specified (timeout is false), the macro sends the contents of the system variable userid to the host and ends. The userid variable must be defined in the session profile for the session running this macro.

Sending a Reply to the Host

Many of the examples in this section use the reply statement to respond to the host. The reply statement lets you send a string of text to the host. If you use the statement without a text string argument, only a carriage return is sent. You can concatenate more than one string in a reply statement by using the plus symbol (+) to join the strings, as shown in the following example:

```
reply userid + " " + password
```
Communicating with a User

In addition to interacting with a host, your macros may also have to communicate with a user. CASL has several language elements specifically designed for interfacing with a user: print, message, input, alert, and dialogbox...enddialog.

Displaying Information

Use the print statement to display information in the session window. You can display constants, variables, or a combination of the two. You can also control such display characteristics as attributes for bright or flashing characters and for color. Note that attributes will work only if the terminal type, which controls the interface between the macro and a terminal, understands what the attributes mean.

The following are examples of simple print statements:

print "Greetings."
print time(cursecond)
print "The time is "; time(cursecond)
print "This is all on the ";
print "same line."

The first example displays the phrase Greetings. The second and third examples display the time. Note that the print statement in the third example contains a semicolon. The semicolon causes the text string and the time to be displayed with no space between them.

The fourth example shows how to use the semicolon at the end of a print statement to suppress a carriage return. In this example, both print statements display text strings that appear on the same line of the screen.

You create a more complex print statement when you display words with an attribute, as shown in the following example:

print "This is a ";bright;"bright ";...
      normal;"idea!"
Chapter 4 Interacting with the Host, Users, and Other Macros

In this example, the bright option is used to display the word bright using the bright attribute. When an attribute is set, it remains in effect until another attribute is specified. In the example, the normal option resets the attribute to normal.

A special character, \^G, causes the PC to beep when the print statement is executed. The reason for this is that the print statement can print ASCII control characters. This attribute is shown in the following example:

```
print "Beep!\^G"
```

The \^G in the example is the ASCII decimal 07 or Bell. For a list of other ASCII control characters, refer to "ASCII Control Codes" on page 40.

Requesting Information

Use the input statement to obtain information from the user. The input statement suspends the macro while waiting for the user to enter data. When the user presses Enter, input knows that data entry is complete. The data entered is stored in a specified variable.

The following example shows how to use the input statement:

```
string user_name

print "Please enter your name: ";
input user_name
print "Hello, "; user_name
```

In the previous example, user_name is declared as a string variable. Since the input statement does not display a prompt, the print statement requests the user to enter a name. After the user enters a name and presses Enter, the entry is stored in the string variable user_name. This variable is then used in the last print statement to display the name that was entered.

The alert and dialogbox...enddialog statements let you create dialog boxes for text input. The alert statement displays a simple dialog box in which the user can enter text or respond by clicking a button. The dialogbox...enddialog construct lets you create more sophisticated dialog boxes, which can contain buttons, text, edit boxes, radio buttons, check boxes, list boxes, and so on.

The following is an example of an alert statement that displays a message:

```
alert "File not found", "Try again", cancel, ok
```
In this example, the message File not found appears in the dialog box. The user can click either Try Again, Cancel, or OK to exit the dialog box.

For additional information about the print, message, input, alert, and dialogbox...enddialog statements, refer to Chapter "CASL Language."
Invoking Other Macros

With CASL, you can invoke, or start, another macro from your macro. Depending on your programming requirements, your macro can terminate and pass control (chain) to the other macro; or your macro can use the do statement to call the other macro as a child macro.

Chaining to Another Macro

To pass control to another macro without returning control to your macro, use the chain statement. For example, to pass control to a macro called SCRIPT2, write the chain statement as follows:

chain "SCRIPT2"

Note: Any statements that follow the chain statement are not executed.

Calling Another Macro

To call another macro as a child macro, use the do statement. When you use this statement, the child macro returns control to the parent macro when the child macro has completed. The following is an example of the do statement:

do "cvtsrc"

Passing Arguments

To pass arguments to the invoked macro, add the arguments to the chain or do statement after the name of the macro. In the following chain statement, the argument CSERVE is passed to SCRIPT2:

chain "SCRIPT2 CSERVE"

To retrieve the arguments in the invoked macro, use the arg function. Use arg with no arguments (or an argument of 0) to retrieve the arguments as one long string. Use arg(1) through arg(n) to retrieve each individual argument.
Exchanging Variables

If you use the `do` statement to invoke another macro, the macros can exchange variable information. To pass a variable between macros, declare the variable as `public` in the invoking macro and as `external` in the invoked macro.

In the following example, the invoking macro, `SCRIPT1`, declares the string variable `myname` as `public`, invokes `SCRIPT2`, prints a message when `SCRIPT2` returns control, and ends.

```plaintext
public string myname
do "SCRIPT2"
print "My name is " + myname
end
```

In the next example, `SCRIPT2`, which was invoked by `SCRIPT1`, declares the string variable `myname` as `external`, assigns a value to `myname`, and returns control to `SCRIPT1`. Note that the value `SCRIPT2` assigns to `myname` is what `SCRIPT1` prints when it regains control (see the first example).

```plaintext
external string myname
myname = "Bert"
end
```

The message that `SCRIPT1` displays on the screen is as follows:

My name is Bert

**Note:** You cannot exchange data with another macro if you use the `chain` statement to invoke the macro. Also, if you are using `public` and `external` variables, you must declare the variable as `public` in the parent macro.
Error trapping makes a macro capable of handling almost any situation, and it is essential in macros that are interfacing with other resources. With error trapping, you can control many different situations. For example, you can set up recovery procedures if a file transfer or file input/output operation fails.

### Enabling Error Trapping

Use the `trap` compiler directive to enable and disable error trapping in your macro. The default setting for this directive is `trap off`. If `trap is off`, a dialog box appears automatically and the macro ends whenever a fatal error occurs. If `trap is on`, the dialog box does not appear, and the macro continues running.

In general, it is best to turn trapping on just prior to a statement that may generate an error and then turn it off after testing for the error. Be sure to check the error-trapping function `error`, the system variables `errclass`, and `errno` just after the statement executes. Otherwise, you may lose the error information if a subsequent statement resets the error function and variables.

### Testing if an Error Occurred

Use the `error` function to test if an error occurred. This function returns `true` if an error occurs or `false` if no error occurs. When you test the function, its value is reset to 0. To continue to trap errors throughout the execution of the macro, you must test (reset) the `error` function each time an error occurs.

### Checking the Type of Error

Use the `errclass` system variable to check the type of error that occurred. This variable contains 0 if no error occurs. If an error does occur, it contains an integer value that reflects the type of error. This variable is not reset when you check its value; the value remains unchanged until another error occurs. For information on the `errclass` values you may encounter, refer to “Classes of Error Message” on page 380.

### Checking the Error Number

Use the `errno` system variable to check the number of the error that occurred. The error number is associated with the type of error that is returned by the `errclass` system variable. For example, the return code 13-08 represents the `errclass` value 13 and the `errno` value 08. This type of error is a file I/O read error. For additional information, refer to Appendix A, “Error Messages.”
If no error occurs, the `errno` variable contains 0. This variable is not reset when you check its value; the value remains unchanged until a different error occurs.

When setting up your macro to trap and handle errors, follow these guidelines in the order shown:

- Set `trap on` right before a statement that could generate an error condition (for example, a statement that sends files to the host). Note that setting `trap on` suppresses error message display.
- Set `trap off` immediately after the statement executes.
- Check the `error` function after setting `trap off`.
- If an error occurs (`error is true`), check the `errclass` and `errno` system variables to determine the error type and number.

The following sample macro illustrates how to use CASL's error trapping capabilities. The script's purpose is to send a file to the host. If the file transfer is successful, the macro ends. If for any reason the file transfer does not complete successfully, the macro sounds an alarm and prints an error message.

```plaintext
/* Macro to send a file. */

string fname
fname = "*.exe"

trap on -- turn on error trapping
send fname -- send the file
trap off -- turn off error trapping
if error then
{
  alarm
  print "Send failed. Error: "; + ...
  errclass; ";-"; errno
}
end
```

This macro is very simple. Ideally, your error handling should be more comprehensive. For example, if the macro is unattended, error handling should either attempt to send the file again or hang up and retry later, depending on the error type. If the macro is attended, error handling might print a message that informs the user of the error and instructs the user to correct the problem and retry the file transfer.
Chapter 4 Interacting with the Host, Users, and Other Macros

It is not always necessary to determine the values in `errclass` and `errno`; sometimes it is sufficient just to know that an error occurred (by checking `error`). How you use error trapping and to what extent depends on what your macro needs to accomplish.

Refer to Chapter 6, “CASL Language,” for more information on the `trap` compiler directive, the `error` function, and the `errclass` and `errno` system variables.
Functional Purpose of CASL Elements

In This Chapter

This chapter groups CASL macro elements by function and includes the following headings:

- Overview ................................................................. 96
- Date and Time Operations ................................. 97
- Error Control ............................................................ 98
- File Input/Output Operations ............................. 99
- Host Interaction ......................................................... 101
- Macro Management ............................................... 102
- Mathematical Operations ...................................... 103
- Printer Control ........................................................ 104
- Program Flow Control ............................................. 105
- Session Management ............................................... 107
- String Operations ..................................................... 109
- Type Conversion Operations ................................. 111
- Window Control ....................................................... 112
- Miscellaneous Elements ....................................... 114
Overview

This chapter contains a quick reference to all of the CASL elements. Detailed descriptions of the elements and examples showing how to use them are covered in Chapter, “CASL Language.”

In this chapter, CASL elements are grouped according to their functional purpose, such as session management, program flow control, file input/output operations, and so on. Some elements might appear more than once if they have more than one purpose. A brief description of the element is also included. Each description ends with an element identifier, as follows:

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Macro Element Group</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td>Function</td>
</tr>
<tr>
<td>S</td>
<td>Statement</td>
</tr>
<tr>
<td>V</td>
<td>Variable (system and module)</td>
</tr>
<tr>
<td>C</td>
<td>Constant</td>
</tr>
<tr>
<td>D</td>
<td>Declaration (procedure and function)</td>
</tr>
<tr>
<td>CD</td>
<td>Compiler directive</td>
</tr>
</tbody>
</table>
Date and Time Operations

The following CASL elements determine the date and time:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>curday</td>
<td>Returns the current day of the month. (F)</td>
</tr>
<tr>
<td>curhour</td>
<td>Returns the current hour. (F)</td>
</tr>
<tr>
<td>curminute</td>
<td>Returns the current minute. (F)</td>
</tr>
<tr>
<td>curmonth</td>
<td>Returns the number of the current month. (F)</td>
</tr>
<tr>
<td>cursecond</td>
<td>Returns the current second. (F)</td>
</tr>
<tr>
<td>curyear</td>
<td>Returns the current year. (F)</td>
</tr>
<tr>
<td>date</td>
<td>Returns today’s date as a string. (F)</td>
</tr>
<tr>
<td>hms</td>
<td>Returns a string in hours, minutes, and seconds format. (F)</td>
</tr>
<tr>
<td>secno</td>
<td>Returns the number of seconds since midnight. (F)</td>
</tr>
<tr>
<td>time</td>
<td>Returns the current time as a string. (F)</td>
</tr>
<tr>
<td>weekday</td>
<td>Returns the number of the day of the week (0–6). (F)</td>
</tr>
</tbody>
</table>
## Error Control

The following CASL elements control error conditions:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>errclass</td>
<td>Indicates the class of the last error. (V)</td>
</tr>
<tr>
<td>errno</td>
<td>Indicates the type of the last error. (V)</td>
</tr>
<tr>
<td>error</td>
<td>Indicates the occurrence of an error. (F)</td>
</tr>
<tr>
<td>trap</td>
<td>Turns error trapping on and off. (CD)</td>
</tr>
</tbody>
</table>
Chapter 5 Functional Purpose of CASL Elements

File Input/Output Operations

The following CASL elements provide file input and output capabilities:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>backups</td>
<td>Determines what is done with duplicate files after a file transfer. (V)</td>
</tr>
<tr>
<td>chdir</td>
<td>Changes to a different disk directory. (S)</td>
</tr>
<tr>
<td>close</td>
<td>Closes a disk file. (S)</td>
</tr>
<tr>
<td>copy</td>
<td>Copies a file or group of files. (S)</td>
</tr>
<tr>
<td>curdir</td>
<td>Returns the current disk directory. (F)</td>
</tr>
<tr>
<td>curdrive</td>
<td>Returns the current disk drive. (F)</td>
</tr>
<tr>
<td>definput</td>
<td>Contains the default input file number. (V)</td>
</tr>
<tr>
<td>defoutput</td>
<td>Contains the default output file number. (V)</td>
</tr>
<tr>
<td>delete</td>
<td>Deletes disk files. (S)</td>
</tr>
<tr>
<td>drive</td>
<td>Sets the current disk drive. (S)</td>
</tr>
<tr>
<td>eof</td>
<td>Returns true if end-of-file is reached. (F)</td>
</tr>
<tr>
<td>eol</td>
<td>Returns true if end-of-line is reached. (F)</td>
</tr>
<tr>
<td>exists</td>
<td>Returns true if a file exists. (F)</td>
</tr>
<tr>
<td>filefind</td>
<td>Locates files in the directory. (F)</td>
</tr>
<tr>
<td>filesize</td>
<td>Returns the file size. (F)</td>
</tr>
<tr>
<td>fncheck</td>
<td>Checks the validity of a file name. (F)</td>
</tr>
<tr>
<td>fnstrip</td>
<td>Returns specified portions of a file name. (F)</td>
</tr>
<tr>
<td>get</td>
<td>Reads characters from a random access file. (S)</td>
</tr>
<tr>
<td>loc</td>
<td>Returns a file pointer position. (F)</td>
</tr>
<tr>
<td>mkdir</td>
<td>Creates a new directory. (S)</td>
</tr>
<tr>
<td>open</td>
<td>Opens a disk file. (S)</td>
</tr>
<tr>
<td>put</td>
<td>Writes records to a random disk file. (S)</td>
</tr>
<tr>
<td>read</td>
<td>Reads text fields from a file. (S)</td>
</tr>
<tr>
<td>readline</td>
<td>Reads text lines from a file. (S)</td>
</tr>
</tbody>
</table>
### Chapter 5 Functional Purpose of CASL Elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>receive</td>
<td>Initiates a file transfer. (S)</td>
</tr>
<tr>
<td>rename</td>
<td>Renames disk files. (S)</td>
</tr>
<tr>
<td>rmdir</td>
<td>Removes a disk directory. (S)</td>
</tr>
<tr>
<td>seek</td>
<td>Moves a file pointer to a specified position. (S)</td>
</tr>
<tr>
<td>send</td>
<td>Initiates a file transfer to a remote computer. (S)</td>
</tr>
<tr>
<td>write</td>
<td>Writes text fields to a file. (S)</td>
</tr>
<tr>
<td>write line</td>
<td>Writes text lines to a file. (S)</td>
</tr>
</tbody>
</table>
### Host Interaction

The following CASL elements let you interact with a host:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>display</td>
<td>Controls the display of incoming characters. (V)</td>
</tr>
<tr>
<td>match</td>
<td>Specifies the string found by the last wait or watch statement. (V)</td>
</tr>
<tr>
<td>nextchar</td>
<td>Returns the next character from a communications device. (F)</td>
</tr>
<tr>
<td>nextline</td>
<td>Returns the next line, delimited by a carriage return, from the communications device. (F/S)</td>
</tr>
<tr>
<td>online</td>
<td>Returns true if a session is online. (F)</td>
</tr>
<tr>
<td>press</td>
<td>Sends a series of keystrokes to the terminal module. (S)</td>
</tr>
<tr>
<td>reply</td>
<td>Sends a string of text to the communications device. (S)</td>
</tr>
<tr>
<td>sendbreak</td>
<td>Sets the length of a break signal. (S)</td>
</tr>
<tr>
<td>track</td>
<td>Watches for string patterns or keystrokes while online. (S)</td>
</tr>
<tr>
<td>wait</td>
<td>Waits for a string of text from the communications device or for a keystroke. (S)</td>
</tr>
<tr>
<td>watch...endwatch</td>
<td>Watches for one of several conditions to occur. (S)</td>
</tr>
</tbody>
</table>
The following CASL elements manage CASL macros:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chain</td>
<td>Passes control to another macro. (S)</td>
</tr>
<tr>
<td>compile</td>
<td>Compiles a macro. (S)</td>
</tr>
<tr>
<td>do</td>
<td>Starts another macro and waits for it to return control. (S)</td>
</tr>
<tr>
<td>genlabels</td>
<td>Specifies whether to include or exclude label information in a compiled macro. (CD)</td>
</tr>
<tr>
<td>genlines</td>
<td>Specifies whether to include or exclude line information in a compiled macro. (CD)</td>
</tr>
<tr>
<td>include</td>
<td>Includes an external file in a compiled macro. (CD)</td>
</tr>
<tr>
<td>inscript</td>
<td>Checks for labels in a macro. (F)</td>
</tr>
<tr>
<td>quit</td>
<td>Closes a session window. (S)</td>
</tr>
<tr>
<td>scriptdesc</td>
<td>Defines a macro description. (CD)</td>
</tr>
<tr>
<td>startup</td>
<td>Contains the name of the macro to run at start-up. (V)</td>
</tr>
<tr>
<td>terminate</td>
<td>Terminates Accessory Manager. (S)</td>
</tr>
<tr>
<td>trace</td>
<td>Turns tracing on and off. (S)</td>
</tr>
</tbody>
</table>
# Mathematical Operations

The following CASL elements perform mathematical operations:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abs</td>
<td>Returns the absolute value of a number. (F)</td>
</tr>
<tr>
<td>cksum</td>
<td>Returns the checksum of a string. (F)</td>
</tr>
<tr>
<td>crc</td>
<td>Returns the CRC of a string. (F)</td>
</tr>
<tr>
<td>intval</td>
<td>Returns the integer value of a string. (F)</td>
</tr>
<tr>
<td>max</td>
<td>Returns the larger of two values. (F)</td>
</tr>
<tr>
<td>min</td>
<td>Returns the smaller of two values. (F)</td>
</tr>
<tr>
<td>mkint</td>
<td>Converts numeric strings to integers. (F)</td>
</tr>
<tr>
<td>val</td>
<td>Returns the real (floating point) value of a string. (F)</td>
</tr>
</tbody>
</table>
Printer Control

The following CASL elements control how data is printed:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>capture</td>
<td>Sends a continuous stream of data from the host to a file. (S)</td>
</tr>
<tr>
<td>footer</td>
<td>Specifies the footer used when printing. (V)</td>
</tr>
<tr>
<td>grab</td>
<td>Sends the contents of the session window to a file. (S)</td>
</tr>
<tr>
<td>header</td>
<td>Specifies the header used when printing. (V)</td>
</tr>
<tr>
<td>lprint</td>
<td>Sends a string of text to the printer. (S)</td>
</tr>
<tr>
<td>printer</td>
<td>Sends a continuous stream of data from the host to a printer. (V)</td>
</tr>
</tbody>
</table>

If you use a CASL macro that contains the PRINTER=ON, PRINTER=OFF, or CAPTURE NEW commands, the Capture Mode must be Raw. To set this option, click Capture from the File menu, click Options, click Raw, click OK, and then click OK again.
Program Flow Control

The following CASL elements provide program flow control:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>case...endcase</td>
<td>Performs statements based on the value of a specified expression. (S)</td>
</tr>
<tr>
<td>chain</td>
<td>Passes control to another macro. (S)</td>
</tr>
<tr>
<td>do</td>
<td>Starts another macro and waits until it returns control. (S)</td>
</tr>
<tr>
<td>end</td>
<td>Ends a macro. (S)</td>
</tr>
<tr>
<td>exit</td>
<td>Exits a procedure. (S)</td>
</tr>
<tr>
<td>for...next</td>
<td>Performs a series of statements a specified number of times, usually while changing the value of a variable. (S)</td>
</tr>
<tr>
<td>freetrack</td>
<td>Returns the value of the lowest unused track number for the current session. (F)</td>
</tr>
<tr>
<td>func...endfunc</td>
<td>A function declaration. (D)</td>
</tr>
<tr>
<td>gosub...return</td>
<td>Transfers program control to a subroutine. (S)</td>
</tr>
<tr>
<td>goto</td>
<td>Transfers program control to a label or expression. (S)</td>
</tr>
<tr>
<td>halt</td>
<td>Stops a macro and its related parent and child macros. (S)</td>
</tr>
<tr>
<td>if...then...else</td>
<td>Controls program flow based on the value of an expression. (S)</td>
</tr>
<tr>
<td>label</td>
<td>Denotes a named reference point in a macro. (S)</td>
</tr>
<tr>
<td>perform</td>
<td>Calls a procedure. (S)</td>
</tr>
<tr>
<td>proc...endproc</td>
<td>A procedure declaration. (D)</td>
</tr>
<tr>
<td>quit</td>
<td>Closes a session window. (S)</td>
</tr>
<tr>
<td>repeat...until</td>
<td>Repeats a statement or series of statements until a specified condition is true. (S)</td>
</tr>
<tr>
<td>return</td>
<td>Returns a value from a function. (S)</td>
</tr>
<tr>
<td>terminate</td>
<td>Terminates Accessory Manager. (S)</td>
</tr>
<tr>
<td>timeout</td>
<td>Returns the status of the most recent wait or watch statement. (V)</td>
</tr>
</tbody>
</table>
### Chapter 5 Functional Purpose of CASL Elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>trace</td>
<td>Turns tracing on and off. (S)</td>
</tr>
<tr>
<td>track</td>
<td>Watches for string patterns or keystrokes while online. (S)</td>
</tr>
<tr>
<td>wait</td>
<td>Waits for a string of text from the communications device or for a keystroke. (S)</td>
</tr>
<tr>
<td>watch...endwatch</td>
<td>Watches for one of several conditions to occur. (S)</td>
</tr>
<tr>
<td>while...wend</td>
<td>Performs a statement or group of statements as long as a specified condition is true. (S)</td>
</tr>
</tbody>
</table>
**Chapter 5 Functional Purpose of CASL Elements**

### Session Management

The following CASL elements manage sessions:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>activate</td>
<td>Activates Accessory Manager by moving the focus to it. (S)</td>
</tr>
<tr>
<td>activatesession</td>
<td>Makes the specified session active. (S)</td>
</tr>
<tr>
<td>assume</td>
<td>Controls the way the CASL compiler handles module variables for the Connection, Terminal, and File Transfer tools. (S)</td>
</tr>
<tr>
<td>bye</td>
<td>Disconnects the current session. (S)</td>
</tr>
<tr>
<td>description</td>
<td>Describes a session. (V)</td>
</tr>
<tr>
<td>device</td>
<td>Specifies a connection device. (V)</td>
</tr>
<tr>
<td>go</td>
<td>Initiates a connection to a communications device. (S)</td>
</tr>
<tr>
<td>keys</td>
<td>Reads or sets the keyboard map to use. (V)</td>
</tr>
<tr>
<td>name</td>
<td>Contains the name of the current session. (F)</td>
</tr>
<tr>
<td>netid</td>
<td>Contains the network identifier for a session. (V)</td>
</tr>
<tr>
<td>new</td>
<td>Creates or opens a session. (S)</td>
</tr>
<tr>
<td>ontime</td>
<td>Indicates how long a session has been online. (F)</td>
</tr>
<tr>
<td>password</td>
<td>Contains the password for the current session. (V)</td>
</tr>
<tr>
<td>protocol</td>
<td>Specifies a file transfer protocol. (V)</td>
</tr>
<tr>
<td>quit</td>
<td>Closes a session window. (S)</td>
</tr>
<tr>
<td>run</td>
<td>Starts another application. (S)</td>
</tr>
<tr>
<td>save</td>
<td>Saves the current session parameters. (S)</td>
</tr>
<tr>
<td>script</td>
<td>Specifies the name of the macro file to use for the current session. (V)</td>
</tr>
<tr>
<td>session</td>
<td>Returns the session number of the current session. (F)</td>
</tr>
<tr>
<td>sessname</td>
<td>Returns the name of the session identified by a specified session number. (F)</td>
</tr>
<tr>
<td>sessno</td>
<td>Returns the session number of a specified session. (F)</td>
</tr>
</tbody>
</table>
## Functional Purpose of CASL Elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>startup</td>
<td>Contains the name of the macro to run at start-up. (V)</td>
</tr>
<tr>
<td>terminal</td>
<td>Specifies the terminal emulation to use. (V)</td>
</tr>
<tr>
<td>terminate</td>
<td>Terminates Accessory Manager. (S)</td>
</tr>
<tr>
<td>userid</td>
<td>Contains the user account name for a session. (V)</td>
</tr>
</tbody>
</table>
## Chapter 5 Functional Purpose of CASL Elements

### String Operations

The following CASL elements perform string operations:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arg</td>
<td>Returns command line arguments. (F)</td>
</tr>
<tr>
<td>bitstrip</td>
<td>Removes bits from strings. (F)</td>
</tr>
<tr>
<td>count</td>
<td>Returns the number of occurrences of one string within another string. (F)</td>
</tr>
<tr>
<td>dehex</td>
<td>Converts ASCII strings in hexadecimal format to binary. (F)</td>
</tr>
<tr>
<td>delete</td>
<td>Returns a string with characters removed. (F)</td>
</tr>
<tr>
<td>destore</td>
<td>Converts strings of printable ASCII characters back to embedded control-character form. (F)</td>
</tr>
<tr>
<td>detext</td>
<td>Converts 7-bit ASCII character strings to binary. (F)</td>
</tr>
<tr>
<td>enhex</td>
<td>Converts a binary string to a string of ASCII characters in hexadecimal format. (F)</td>
</tr>
<tr>
<td>enstore</td>
<td>Converts strings with embedded control characters into strings of printable ASCII characters. (F)</td>
</tr>
<tr>
<td>entext</td>
<td>Converts a string of binary data to a string of 7-bit ASCII characters. (F)</td>
</tr>
<tr>
<td>hex</td>
<td>Converts an integer to a hexadecimal string. (F)</td>
</tr>
<tr>
<td>hms</td>
<td>Returns a string in hours, minutes, and seconds format. (F)</td>
</tr>
<tr>
<td>inject</td>
<td>Changes some characters in a string. (F)</td>
</tr>
<tr>
<td>insert</td>
<td>Adds characters to a string. (F)</td>
</tr>
<tr>
<td>instr</td>
<td>Looks for a substring in a string. (F)</td>
</tr>
<tr>
<td>intval</td>
<td>Returns the integer value of a string. (F)</td>
</tr>
<tr>
<td>left</td>
<td>Returns the left portion of a string. (F)</td>
</tr>
<tr>
<td>length</td>
<td>Returns the length of a string. (F)</td>
</tr>
<tr>
<td>lowercase</td>
<td>Changes a string to all lowercase characters. (F)</td>
</tr>
<tr>
<td>mid</td>
<td>Returns a middle portion of a string. (F)</td>
</tr>
<tr>
<td>mkstr</td>
<td>Converts an integer to a string. (F)</td>
</tr>
</tbody>
</table>
### Chapter 5 Functional Purpose of CASL Elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>null</td>
<td>Returns true if a string has zero length. (F)</td>
</tr>
<tr>
<td>pack</td>
<td>Removes duplicate characters from a string. (F)</td>
</tr>
<tr>
<td>pad</td>
<td>Adds extra characters to a string. (F)</td>
</tr>
<tr>
<td>quote</td>
<td>Returns a string enclosed in quotation marks. (F)</td>
</tr>
<tr>
<td>right</td>
<td>Returns the right portion of a string. (F)</td>
</tr>
<tr>
<td>slice</td>
<td>Breaks out portions of a string. (F)</td>
</tr>
<tr>
<td>str</td>
<td>Converts a number to string format. (F)</td>
</tr>
<tr>
<td>strip</td>
<td>Returns a string with certain characters removed. (F)</td>
</tr>
<tr>
<td>subst</td>
<td>Returns a string with certain characters changed. (F)</td>
</tr>
<tr>
<td>upcase</td>
<td>Changes a string to all uppercase characters. (F)</td>
</tr>
<tr>
<td>val</td>
<td>Returns the real (floating point) value of a string. (F)</td>
</tr>
<tr>
<td>winstring</td>
<td>Reads a string from a window. (F)</td>
</tr>
</tbody>
</table>
Chapter 5 Functional Purpose of CASL Elements

Type Conversion Operations

The following CASL elements convert data from one type to another:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asc</td>
<td>Returns the ASCII value of a string. (F)</td>
</tr>
<tr>
<td>binary</td>
<td>Converts a string to a binary number. (F)</td>
</tr>
<tr>
<td>bitstrip</td>
<td>Strips bits from strings. (F)</td>
</tr>
<tr>
<td>chr</td>
<td>Returns a single-character string for an ASCII value. (F)</td>
</tr>
<tr>
<td>class</td>
<td>Returns the class type of a single-character string. (F)</td>
</tr>
<tr>
<td>dehex</td>
<td>Converts ASCII strings in hexadecimal format to binary. (F)</td>
</tr>
<tr>
<td>detext</td>
<td>Converts 7-bit ASCII character strings to binary. (F)</td>
</tr>
<tr>
<td>enhex</td>
<td>Converts a binary string to a string of ASCII characters in hexadecimal format. (F)</td>
</tr>
<tr>
<td>entext</td>
<td>Converts a string of binary data to a string of 7-bit ASCII characters. (F)</td>
</tr>
<tr>
<td>hex</td>
<td>Converts an integer to a hexadecimal string. (F)</td>
</tr>
<tr>
<td>intval</td>
<td>Returns the integer value of a string. (F)</td>
</tr>
<tr>
<td>mkint</td>
<td>Converts numeric strings to integers. (F)</td>
</tr>
<tr>
<td>mkstr</td>
<td>Converts an integer to a string. (F)</td>
</tr>
<tr>
<td>octal</td>
<td>Converts a decimal integer to an octal integer. (F)</td>
</tr>
<tr>
<td>str</td>
<td>Converts a number to string format. (F)</td>
</tr>
<tr>
<td>val</td>
<td>Returns the real (floating point) value of a string. (F)</td>
</tr>
</tbody>
</table>
## Window Control

The following CASL elements control the window size and how data is input and displayed in a window:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>activate</td>
<td>Activates Accessory Manager window by moving the focus to it. (S)</td>
</tr>
<tr>
<td>alert</td>
<td>Creates simple dialog boxes for display on the screen. (S)</td>
</tr>
<tr>
<td>choice</td>
<td>Contains the value of the button that dismissed a dialog box. (V)</td>
</tr>
<tr>
<td>clear</td>
<td>Clears a window. (S)</td>
</tr>
<tr>
<td>dialogbox...enddialog</td>
<td>Creates more complex dialog boxes for display on the screen. (S)</td>
</tr>
<tr>
<td>hide</td>
<td>Reduces a session window to an icon. (S)</td>
</tr>
<tr>
<td>hideallquickpads</td>
<td>Hides all of the QuickPads. (S)</td>
</tr>
<tr>
<td>hidequickpad</td>
<td>Hides a QuickPad. (S)</td>
</tr>
<tr>
<td>input</td>
<td>Accepts input from the screen. (S)</td>
</tr>
<tr>
<td>loadquickpad</td>
<td>Activates a QuickPad. (S)</td>
</tr>
<tr>
<td>maximize</td>
<td>Enlarges the Accessory Manager window to full-screen size. (S)</td>
</tr>
<tr>
<td>minimize</td>
<td>Reduces the Accessory Manager window to an icon. (S)</td>
</tr>
<tr>
<td>move</td>
<td>Moves the Accessory Manager window to a new location on the screen. (S)</td>
</tr>
<tr>
<td>passchar</td>
<td>Specifies the character to display in a text box on a dialog box created using dialogbox...enddialog and the secret option. (V)</td>
</tr>
<tr>
<td>print</td>
<td>Displays information on the screen. (S)</td>
</tr>
<tr>
<td>restore</td>
<td>Restores the Accessory Manager window to its original size. (S)</td>
</tr>
<tr>
<td>show</td>
<td>Redisplays a session window. (S)</td>
</tr>
<tr>
<td>showquickpad</td>
<td>Displays a QuickPad. (S)</td>
</tr>
</tbody>
</table>
### Chapter 5 Functional Purpose of CASL Elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>size</td>
<td>Changes the size of a window. (S)</td>
</tr>
<tr>
<td>tabwidth</td>
<td>Specifies the number of spaces a tab character moves the cursor. (V)</td>
</tr>
<tr>
<td>unloadallquickpads</td>
<td>Closes all of the QuickPads. (S)</td>
</tr>
<tr>
<td>unloadquickpad</td>
<td>Closes a QuickPad. (S)</td>
</tr>
<tr>
<td>winchar</td>
<td>Reads a character from a window. (F)</td>
</tr>
<tr>
<td>winsizex</td>
<td>Returns the horizontal size of a window. (F)</td>
</tr>
<tr>
<td>winsizey</td>
<td>Returns the vertical size of a window. (F)</td>
</tr>
<tr>
<td>winstring</td>
<td>Reads a character string from a window.</td>
</tr>
<tr>
<td>xpos</td>
<td>Returns the horizontal location of the cursor. (F)</td>
</tr>
<tr>
<td>ypos</td>
<td>Returns the vertical location of the cursor. (F)</td>
</tr>
<tr>
<td>zoom</td>
<td>Enlarges a session window to the size of the Accessory Manager application window. (S)</td>
</tr>
</tbody>
</table>
Chapter 5 Functional Purpose of CASL Elements

Miscellaneous Elements

The following are CASL elements that don’t fall into the preceding categories:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alarm</td>
<td>Sounds an alarm at the terminal. (S)</td>
</tr>
<tr>
<td>busycursor</td>
<td>Displays the cursor as an hourglass. (S)</td>
</tr>
<tr>
<td>environ</td>
<td>Returns environment variables. (F)</td>
</tr>
<tr>
<td>false</td>
<td>Sets a variable to logical false. (C)</td>
</tr>
<tr>
<td>freemem</td>
<td>Returns the amount of available memory. (F)</td>
</tr>
<tr>
<td>inkey</td>
<td>Returns the value of a keystroke. (F)</td>
</tr>
<tr>
<td>off</td>
<td>Sets an item to logical false. (C)</td>
</tr>
<tr>
<td>on</td>
<td>Sets an item to logical true. (C)</td>
</tr>
<tr>
<td>pop</td>
<td>Discards a return address from the stack. (S)</td>
</tr>
<tr>
<td>review</td>
<td>Defines the size of the review buffer. (V)</td>
</tr>
<tr>
<td>stroke</td>
<td>Waits for the next keystroke from the keyboard. (F)</td>
</tr>
<tr>
<td>systime</td>
<td>Indicates how long the current session has been active. (F)</td>
</tr>
<tr>
<td>true</td>
<td>Sets a variable to logical true. (C)</td>
</tr>
<tr>
<td>version</td>
<td>Returns the Accessory Manager version number. (F)</td>
</tr>
<tr>
<td>winversion</td>
<td>Returns the Windows version number. (F)</td>
</tr>
</tbody>
</table>
This chapter provides detailed information about all CASL elements, including the syntax of each element and examples of how the element can be used.

How CASL Elements Are Documented

In this chapter, all CASL elements are listed in alphabetical order. (For a summary of CASL elements grouped by function, refer to Chapter 5, “Functional Purpose of CASL Elements.”)

The name of each CASL element appears as a heading at the top of the page. The type of element it is (such as function, statement, system variable, and so on) appears in parentheses.

Immediately below the CASL element name is a brief description of the element and how it should be used, followed by these sections:

- Format—the syntax for the element
  
  **Note**: For a description of the notation used in the format, refer to Chapter 2, “Understanding the Basics of CASL.”

- Comments—additional descriptive information about the element

- Example—an example of how the element can be used

- See Also—a list of other related elements
abs (function)

Use abs to get the absolute value of a number.

Format

\[ x = \text{abs}(\text{expression}) \]

Comments

expression must be a real or signed integer. The result returned by the abs function is always a positive number.

Example 1

positive_number = abs(negative_number)

In this example, abs assigns the absolute value of the contents of negative_number to the variable called positive_number.

Example 2

if abs(net_worth) > 5 then alarm

In this example, an alarm sounds if the absolute value of the net_worth variable is greater than five.

See Also

cksum, crc, intval, max, min, mkint, val
activate (statement)

Use `activate` to make the Accessory Manager application window the active window.

**Format**

`activate`

**Example**

`activate`
activatesession (statement)

Use `activatesession` to make the specified session active.

**Format**

```
activatesession sessionid
```

**Comments**

When you use this statement, the session identified by `sessionid` becomes active.

**Example 1**

```
activatesession sessA
```

In this example, session A becomes active.

**Example 2**

```
activatesession sessno("ABBS")
```

In this example, `activatesession` activates the session named ABBS whose session number is returned by the `sessno` function.

**See Also**

`activate`
alarm (statement)

Use alarm to make the PC sound an alarm.

Format

```
alarm [integer]
```

Comments

This function is useful for getting the user's attention.

`integer` can be any integer between 0 and 5; values outside of this range are treated as 0. Zero is the default value used when no argument is specified.

The sounds produced by `integer` vary, depending on the .WAV files specified in the Windows Registry in `HKEY_CURRENT_USER\AppEvents\Schemes\Apps\Default`. The following table shows possible `integer` values and their corresponding sounds or registry keys:

<table>
<thead>
<tr>
<th>Integer Value</th>
<th>Sound or Registry Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Short beep</td>
</tr>
<tr>
<td>1</td>
<td>System Asterisk\Current</td>
</tr>
<tr>
<td>2</td>
<td>System Exclamation\Current</td>
</tr>
<tr>
<td>3</td>
<td>System Hand\Current</td>
</tr>
<tr>
<td>4</td>
<td>System Question\Current</td>
</tr>
<tr>
<td>5</td>
<td>.Default\Current</td>
</tr>
</tbody>
</table>

If the PC has no sound card, all the alarm values result in a beep through the speaker.

Example 1

```
alarm 1
```

In this example, the PC makes the chord sound.
Example 2

if not exists("BBS.DAT") then alarm

In this example, the \texttt{exists} function is used to determine the existence of a file. If the file does not exist, the macro sounds an alarm.

Example 3

\begin{verbatim}
for i = 0 to 12
    print "alarm "; i
    alarm i
    wait 1 second
next
\end{verbatim}

In this example, the terminal sounds all of the alarms, with a pause of one second between each alarm.
alert (statement)

Use alert to display a dialog box that allows choices to be made.

Format

```plaintext
alert string, button1 [, button2 ... 
   [, button3 [, button4]]] [, str_var]
```

Comments

The alert statement displays a dialog box that prompts the user for input, or notifies the user of some important occurrence.

A text message defined by `string` is centered in the dialog box.

The defined buttons are displayed from left to right along the bottom of the dialog box. For `button1` through `button4`, you can use either the text that you want to display on the button or the predefined keywords `ok` and `cancel`.

If you use text for the buttons, enclose the text in quotation marks. The maximum length of a button name is ten characters.

If you use the predefined keywords `ok` and `cancel`, you do not need to enclose these keywords in quotation marks. If you use the `ok` keyword, alert creates an OK button in the dialog box and associates Enter with this button. If you use the `cancel` keyword, alert creates a Cancel button in the dialog box and associates Esc with this button.

`str_var` is a previously defined string variable that causes alert to display an edit box in which the user can enter text. The edit box appears between the text message string and the buttons in the dialog box.

You can examine the variables that display or store user information after the alert statement has executed. The system variable, `choice`, contains a value between one and four that corresponds to the button used to exit the dialog box. For example, if `button1` is chosen, `choice` is set to integer 1. Note that `str_var` is not updated if the Cancel button is used to exit the dialog box.

Accessory Manager normally makes the first letter of the button name an accelerator. You can define a different accelerator by placing an ampersand (&) to the left of the desired letter. If you use variables for the button names, make sure the OK and Cancel buttons are last; if the last item is a variable, it is used for a text box.
Example 1

```casl
string username

alert "Please enter your name:", ok, username
alert "You entered: " + username, ok
```

In this example, the macro displays a dialog box that prompts the user to enter a name. The name is stored in the variable `username`. A second dialog box displays the contents of `username`.

Example 2

```casl
if not exists(filename) then

    alert "File not found", "Try again", ok, cancel
    if choice = 1 then goto get_fname

```

In this example, the macro displays a dialog box that tells the user an invalid file name has been entered. If the user clicks the Try Again button, the macro branches to its `get_fname` label.

See Also
dialogbox...enddialog
arg (function)

Use arg to check the command-line argument(s) at macro invocation.

Format

\[ x_1 = \text{arg}([\text{integer}]) \]

Comments

arg with no arguments (or an argument of 0) returns all of the arguments that follow the name of a macro in the chain or do statement. For session start-up macros, it can also return everything that was typed in the Arguments text box on the CASL Macro tab on the Session Preferences dialog box, which is accessed from Accessory Manager's Options menu.

\[
\text{arg}(1) \text{ through arg}(n) \text{ return the individual elements of the argument, as separated by commas.}
\]

Example 1

script1.xws

\[
\text{do } \"\text{script2}, \"\text{barkley}\"
\]

script2.xws:

\[
\text{fname = arg}(1)\\
\text{if arg}(1) = \"\text{barkley}\" \text{ then ...}
\]

In this example, the first macro uses the do statement with the argument barkley to start the second macro as a child macro. The second macro assigns the value in arg(1) to the user variable fname. Then it tests whether the first argument is barkley.

Example 2

menu.xws

\[
\text{do } \"\text{LOGIN}, \"\text{myuserid}, \"\text{mypassword}\"
\]

login.xws

\[
\text{reply arg}(1)\\
\text{wait for } \"\text{password:}\"
\text{reply arg}(2)
\]

In this example, the do statement is used to run the macro file LOGIN. LOGIN reads its arguments and sends them to the host with the reply statement.

See Also

chain, do
asc (function)

Use `asc` to convert the first character of a string to its corresponding ASCII value.

**Format**

\[ x = \text{asc}(\text{string}) \]

**Comments**

`string` can be a string constant or expression of any length. When the statement is executed, \( x \) contains the ASCII value of the first character in the string. If `string` is not null, the value returned is in the range of 0–255. If `string` is null (has no length), `asc` returns -1.

**Example 1**

\[ \text{sixty_five} = \text{asc}("A") \]

In this example, `asc` returns the ASCII value of the character `A` in the variable `sixty_five`.

**Example 2**

\[ \text{seventy} = \text{asc}("For pity's sake") \]

In this example, `asc` returns the value of the character `F` (which is the first character of the string, "For pity's sake") in the variable `seventy`.

**Example 3**

\[ x = \text{asc}((\text{mid}(\text{thestring}, 2, 1))) \]

In this example, `asc` converts the second character of `thestring` and returns the result in \( x \).

**See Also**

`binary`
assume (statement)

Use assume to specify which connection, terminal, or file transfer tool is being used by the session.

| Note: EXTRA! Enterprise for Accessory Manager sessions do not support this statement. |

Format

```
assume tool "filename" ... [, module "filename"]
```

Comments

Before you can specify any configuration settings for a connection, terminal, or file transfer tool, you must use the assume statement to indicate which tool is loaded.

```
tool can be either device (for the connection tool), terminal (for the terminal tool) or protocol (for the file transfer tool).
```

```
filename is the name of the tool (it must be enclosed in quotation marks). For the connection tool, the only valid file name is ICSTOOL. For valid terminal tool names, refer to “terminal (system variable)” on page 318. For valid file transfer tool names, refer to “protocol (system variable)” on page 280.
```

For more information about connection, terminal, and file transfer tools, as well as a list of the configuration settings that you can specify for each tool, refer to Chapter 7, “Connection, Terminal, and File Transfer Tools.”

Example

```
assume terminal "DCAT27"
CurShape = "Block"
```

In this example, the macro indicates that the session is a T 27 session and configures the cursor shape to a block.

See Also

device, protocol, terminal
backups (module variable)

Use backups to determine whether to keep or discard duplicate files during file transfers.

| Note: Some file transfer protocols do not use this variable. |

**Format**

```
backups = option
```

**Comments**

`option` is one of the following:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>on</td>
<td>If an existing file is received or edited, the old file is renamed with a .BAK extension. If a backup file already exists, it is deleted.</td>
</tr>
<tr>
<td>off</td>
<td>If an existing file is received or edited, the old copy of the file is deleted.</td>
</tr>
</tbody>
</table>

**Example**

```
backups = off
```

In this example, backups is turned off.
### binary (function)

Use binary to convert an integer to a string, in binary format.

**Format**

\[ x\$ = \text{binary}(\text{integer}) \]

**Comments**

The `binary` function returns a binary string that represents the value of `integer`. The string can be 8, 16, or 32 bytes long, depending on the value of `integer`. Integer values and their corresponding binary string lengths are shown in the following table.

<table>
<thead>
<tr>
<th>Integer Value</th>
<th>Binary String Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>0–255</td>
<td>8</td>
</tr>
<tr>
<td>256–65,535</td>
<td>16</td>
</tr>
<tr>
<td>65,536–2,147,483,64</td>
<td>32</td>
</tr>
</tbody>
</table>

**Example**

`bin_num = binary(some_num)`

In this example, the value of the variable `some_num` is converted to its binary form, and the new value is stored in the variable `bin_num`. 
bitstrip (function)

Use bitstrip to strip certain bits from a string.

Format

\[ x = \text{bitstrip}(\text{string} [\ , \ \text{mask}]) \]

Comments

bitstrip produces a new string that is the result of performing a bitwise and of each character in string with mask. Refer to Chapter 2, “Understanding the Basics of CASL,” for an explanation of the bitwise and operation.

mask is an integer bitmap value that defaults to 127 (0x7F), thus stripping the high order bit from each byte in string. Some word processors, such as Microsoft Word, set the high bit in certain characters to indicate various conditions such as special formatting. Stripping the high bit makes such files readable, but it is not a replacement for a true conversion program. A mask of 0x5F (95 decimal) converts lowercase letters to uppercase, but it also changes other characters.

Because mask is a bitmap, it must be in the range of 0–255 (decimal); values in the range of 0–127 are the most useful.

Example 1

readable_string = bitstrip(Word_line)

In this example, bitstrip strips the high-order bit of each byte of the string Word_line and returns the result in readable_string.

Example 2

reply bitstrip(Word_line)

In this example, bitstrip strips the high-order bit of each byte of the string Word_line, and the result is sent to the host with the reply statement.

Example 3

all_upcase = bitstrip("abc", 0x5F)

In this example, the letters abc are converted to ABC.

See Also

lowcase, upcase
busycursor (statement)

Use busycursor to display the cursor as an hourglass when you expect a command to take a noticeable time interval to execute.

Format

busycursor [on | off]

Comments

This statement displays the cursor as an hourglass.

Example

busycursor on

wait 1 minute for "Login", "ID", "Password"
case match of
    "Login": reply logon
    "ID": reply userid
    "Password": reply password
endcase

busycursor off

In this example, the cursor appears as an hourglass while the match function proceeds.
bye (statement)

Use bye to end a connection.

Note: EXTRA! Enterprise for Accessory Manager sessions do not support this statement.

Format  

```plaintext
bye
```

Comments  
This statement immediately disconnects the current session.

Example  

```plaintext
wait for "Logged off" : bye
```

In this example, the macro waits for the phrase "Logged off" and then disconnects the session.

See Also  
quit
capture (statement)

Use capture to send screen output to a file.

Format

\[ \text{capture option [filename]} \]

Comments

In Accessory Manager, clicking Capture from the File menu initiates a continuous capture of data received from the host. The capture statement performs a similar function, controlling whether data is being captured at any particular time.

When you click Capture from the File menu in Accessory Manager, you can specify whether to send the data to a printer or file. In CASL, the destination is determined by the command. Use capture to send a continuous stream of data to a file; use printer to send the data to a printer.

For the capture statement, the macro syntax determines the filename and whether the data in any existing file is overwritten or appended. However, all other settings that affect the operation of the capture (such as whether normal or raw data is captured) are controlled by the options specified on the Capture Options and Advanced Capture Options dialog boxes within Accessory Manager. (To view these dialog boxes, make sure that Show Capture Dialog When Start Capture is selected on the Global Preferences dialog box. Then click Capture from the File menu, and click Options on the Capture Printer Settings dialog box.)

Unless you specify a different drive and directory when you specify the \textit{filename}, all files are created in the ACCMGR32 folder within the INFOConnect folder.

\textit{option} can be any of the following values:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>Starts capture and overwrites the specified file</td>
</tr>
<tr>
<td></td>
<td>If you use the new option, you must specify a \textit{filename}.</td>
</tr>
<tr>
<td>to</td>
<td>Starts capture and appends to the specified file</td>
</tr>
<tr>
<td></td>
<td>If you use the to option, you must specify a \textit{filename}.</td>
</tr>
</tbody>
</table>
### Example 1

**capture on**

In this example, data is captured to a file that is automatically named based on the session name and current date.

### Example 2

**capture new "vutext.txt"**

In this example, data is captured in a file called `vutext.txt`. If a file of that name already exists, its content is overwritten.

### See Also

`grab`, `printer`
**Case...Endcase (Statements)**

Use `case...endcase` to perform statements based on the value of a specified expression.

**Format**

```
  case expression of
    list of values : statement group
    list of values : statement group
    ...
    ...
    [default : statement group]
  endcase
```

**Comments**

- `case` lets you take a variety of actions based on the value of a particular expression. `expression` can be any type of expression or variable. `list of values` is a list of expected values for `expression` and must match the data type of `expression`. The values can be constants or expressions and must be separated by commas if you use more than one value on a logical line.

- `statement group` is a series of statements to perform if one of the items in `list of values` matches the current expression. After the associated `statement group` has been performed, the macro continues to execute at the point after the `endcase` statement (unless control was transferred somewhere else with a `goto` or a `gosub` statement).

- `default` and its associated `statement group` describe a statement or group of statements to perform if none of the other values match. If you include `default`, be sure it is the last item in the list. `endcase` denotes the end of the `case...endcase` construct.

You can nest `case...endcase` statements.
Example 1

label ask_again
print "Please choose a number (0-4): " ;
input choice
print
case choice of
  0, 4 : end
  1 : goto choose_speed
  2 : goto main_menu
  3 : goto save_setup
  default : goto ask_again
endcase

In this example, case examines the value of the integer variable choice. If choice is 0 or 4, the macro ends. If choice has a value between 1 and 3, the macro branches to the appropriate label. If choice is not 0 through 4, the default action is taken. If none of the conditions were met (assuming a default was not provided), the macro would continue execution at the statement following the endcase.

Example 2

case left(date, 5) of
  "08/12" : print "Today is Aaron's birthday!"
  "07/04" : print "Why are you here today?"
  "10/31" : alarm 6 : print "Boo!"
endcase

This example shows that you can use case with any type of expression. The actions taken in this example depend on the date.

See Also
gosub, goto, if...then...else, watch...endwatch

**Chapter 6  CASL Language**

## chain (statement)

Use chain to compile and run a macro.

**Format**

```
chain  filename  [,  args]
```

**Comments**

chain compiles and runs the specified macro source file (XWS) if there is no compiled version of the macro, or if the date of the source file is more current than the date of the compiled version. Otherwise, chain runs the compiled version of the macro.

You do not have to include the macro extension, but you must include the drive and directory where the macro is located.

*args* represents an optional argument list that contains the individual arguments to be passed to the other macro. Individual arguments must be separated by commas.

**Note:** The macro that issues a chain statement ends and is removed from memory; therefore, control cannot be passed back to it.

**Example**

```
chain  "C:\PROGRAM FILES\ATTACHMATE\INFOCN2K\ACCMGR32\MENU",  "arg1",  "arg2"
```

In this example, the macro chains to a macro called **MENU** and passes the macro two arguments.

**See Also**

arg, do
**chdir (statement)**

Use **chdir** to change the current disk directory.

**Format**

```
chdir string
```

**Comments**

*string* must be an expression containing a valid directory name. The current working directory is set to the new value. This does not change the current drive designation.

| Note: You can also use the abbreviation **cd** for this statement. |

**Example 1**

```
chdir "C:\PROGRAM FILES\ATTACHMATE\INFOCN2K\ACCMGR32"
```

In this example, the directory is changed to `C:\PROGRAM FILES\ATTACHMATE\INFOCN2K\ACCMGR32`.

**Example 2**

```
chdir dirname
```

In this example, the directory is changed to the directory name stored in the script's *dirname* variable.

**See Also**

drive
choice (system variable)

Use choice to check the value of the button that dismissed a dialog box.

Format

n = choice

Comments

choice contains the value identifying the button used to exit a dialog box.

Example 1

dialogbox 20, 50, 280, 100
  defpushbutton 10, 10, 80, 80, "Choice 1", ok
  pushbutton 100, 10, 80, 80, "Choice 2", cancel
  pushbutton 190, 10, 80, 80, "Choice 3", focus
enddialog
print "Choice was "; choice

In this example, choice has a value of 1 if the Choice 1 (ok) button is chosen, 2 if the Choice 2 (cancel) button is selected, or 3 if the Choice 3 (focus) button is chosen.

Example 2

dialogbox 20, 50, 280, 100
  pushbutton 100, 10, 80, 80, "Choice 1", cancel
  pushbutton 190, 10, 80, 80, "Choice 2", ok
  defpushbutton 10, 10, 80, 80, "Choice 3", focus
enddialog
print "Choice was "; choice

In this example, choice has a value of 1 if the Choice 1 (cancel) button is chosen, 2 if the Choice 2 (ok) button is selected, or 3 if the Choice 3 (focus) button is chosen.

In both of these examples, the buttons are displayed in the same locations in the dialog box.

See Also

dialogbox...enddialog
chr (function)

Use chr to get a single character string defined by an ASCII value.

Format

\[ x^$ = \text{chr}(\text{integer}) \]

Comments

\text{chr} returns a one-byte string that contains the character with the ASCII value contained in \text{integer}.

\text{integer} is a decimal number that is converted to its Modulo 255 value; therefore, it is in the range of 0–255.

Example 1

\text{cr} = \text{chr}(13)

In this example, the variable \text{cr} is set to ASCII value 13, which is a carriage return.

Example 2

\text{reply} \ \text{chr}(3)

In this example, the ASCII value 3 is sent to the host.
**chksum (function)**

Use *chksum* to get an integer checksum for a string of characters.

**Format**

\[ x = \text{chksum}(\text{string}) \]

**Comments**

*chksum* returns the arithmetic checksum of the characters contained in \textit{string}. \textit{string} can be any length. You can use this function to develop a proprietary file transfer protocol, or to check the integrity of a string transferred between two systems using a non-protocol transfer.

**Example 1**

\[ \text{check} = \text{chksum}(\text{what\_we\_got}) \]

In this example, the checksum value of the \textit{what\_we\_got} variable is stored in the check variable.

**Example 2**

\[ \text{if } \text{chksum(data\_in)} \neq \text{chksum(data\_out)} \text{ then alarm} \]

In this example, an alarm sounds if the checksum of the \textit{data\_in} variable is not the same as the checksum of the \textit{data\_out} variable.

**See Also**

*crc*
class (function)

Use `class` to get the Accessory Manager class value for a single-character string.

**Format**

```plaintext
x = class(string)
```

**Comments**

`class` returns the class number bitmap of the first character in `string`.

The bitmap value returned indicates the class(es) in which the first character in the string falls. Classes define such groupings as capital letters (A–Z), decimal digits (0–9), and hexadecimal digits (0–9 plus A–F or a–f). The following table lists class groupings.

<table>
<thead>
<tr>
<th>Hexadecimal</th>
<th>Decimal</th>
<th>Class Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x01</td>
<td>1</td>
<td>White space (space, tab, CR, LF, FF, BS, null)</td>
</tr>
<tr>
<td>0x02</td>
<td>2</td>
<td>Uppercase alpha (A–Z)</td>
</tr>
<tr>
<td>0x04</td>
<td>4</td>
<td>Lowercase alpha (a–z)</td>
</tr>
<tr>
<td>0x08</td>
<td>8</td>
<td>Legal identifier ($, %, _)</td>
</tr>
<tr>
<td>0x10</td>
<td>16</td>
<td>Decimal digit (0–9)</td>
</tr>
<tr>
<td>0x20</td>
<td>32</td>
<td>Hexadecimal digit (A–F, a–f)</td>
</tr>
<tr>
<td>0x40</td>
<td>64</td>
<td>Delimiters: space, comma, period, tab, {, }, , , ;, &lt;, =, &gt;, !</td>
</tr>
<tr>
<td>0x80</td>
<td>128</td>
<td>Punctuation: !, :-@, [^, {~</td>
</tr>
</tbody>
</table>

A character may fall into more than one class. For example, the comma is both a delimiter and a punctuation mark, and returns a class value of 0xC0 or 192 decimal.

**Example**

```plaintext
x = class(a_char) : if x = 1 then ...  
```

In this example, `a_char` is a white space if `x` is 1.
clear (statement)

Use clear to clear the terminal screen.

Format

clear [window] [, line] [, eow] [, bow] ...
   [, eol] [, bol]

Comments

If no option is specified, the entire session window is cleared, and the cursor moves to the upper-left corner of the window. If an option is specified, the cursor remains in place. The following table explains the options.

<table>
<thead>
<tr>
<th>This option</th>
<th>Clears this</th>
</tr>
</thead>
<tbody>
<tr>
<td>window</td>
<td>The entire window</td>
</tr>
<tr>
<td>line</td>
<td>The line on which the cursor is located</td>
</tr>
<tr>
<td>eow</td>
<td>From the cursor to the end of the window</td>
</tr>
<tr>
<td>bow</td>
<td>From the cursor to the beginning of the window</td>
</tr>
<tr>
<td>eol</td>
<td>From the cursor to the end of the current line</td>
</tr>
<tr>
<td>bol</td>
<td>From the cursor to the beginning of the current line</td>
</tr>
</tbody>
</table>

Example 1

clear bow

In this example, the macro clears the session window from the cursor to the beginning of the window.

Example 2

clear window

In this example, the macro clears the entire session window.
close (statement)

Use close to close an open data file.

Format

```
close [# filenum]
```

Comments

close ends access to an open file. If a filenum is not specified, all open files are closed. (All open files are closed automatically when the macro that opened them terminates.)

The # symbol must precede the file number.

Example

```
close
```

In this example, all open files are closed.

See Also

open
The cls statement, which is a synonym for the clear statement, is supported only for backward compatibility. Refer to “clear (statement)” on page 142.
**compile (statement)**

Use `compile` to compile a macro file.

**Format**

`compile "filename"`

**Comments**

This statement compiles the specified macro. The compiled macro file is saved in the same directory where the source macro is found.

**Example**

`compile "MENU"`

In this example, the macro called MENU is compiled.
connected (function)

The connected function, which is a synonym for the online function, is supported only for backward compatibility. Refer to “online (function)” on page 263.
**copy (statement)**

Use `copy` to copy a file or group of files.

**Format**

```
copy [some] filefrom, fileto
```

`filefrom` must be a legal file name (full path names and wild cards are permitted). `fileto` specifies the new file name for the copy; it defaults to the current directory.

If you specify `some`, the user must approve each file before it is copied.

**Example 1**

```
copy "menu.xts", "menu2.xts"
```

In this example, `MENU.XTS` is copied to `MENU2.XTS`.

**Example 2**

```
copy "*.xts", "*.bak"
```

In this example, the macro copies each file with the `.XTS` extension and gives the copied files a `.BAK` extension.

**Example 3**

```
copy some "*.xts", "A:"
```

In this example, the macro copies all files with the `.XTS` extension to drive `A`, but confirmation is requested of the user before each individual file is copied.
count (function)

Use count to determine the number of occurrences of a character within a string.

**Format**

\[ x = \text{count}(\text{string1}, \text{string2}) \]

**Comments**

count returns the number of times any of the characters in string2 occur in string1. This function can take the place of the instr function in a counting loop to determine how many times your macro must take some future action.

This function is case-sensitive.

**See Also**

instr

**Example 1**

\[ x = \text{count}("sassafras", "s") \]

In this example, count returns the number of times the letter s occurs in the string "sassafras". The result is 4.

**Example 2**

\[ x = \text{count}("sassafras", "sa") \]

In this example, count returns the number of times the letters s and a occur in the string "sassafras". The result is 7.
crc (function)

Use crc to determine the cyclical redundancy check value for a string.

**Format**

\[ x = \text{crc}(\text{string} [, \text{integer}]) \]

**Comments**

\( x \) is returned as the \( \text{crc} \) of \( \text{string} \). The \( \text{crc} \) starts with a value of 0 unless a starting value is given in \( \text{integer} \).

As with the cksum function, you can use \( \text{crc} \) to develop a proprietary file transfer protocol or to check the integrity of a string.

**Example 1**

\[ x = \text{crc}("AM") \]

In this example, \( x \) is assigned the \( \text{crc} \) value of the string \( AM \).

**Example 2**

\[ x = \text{crc}(@text\_line) \]

In this example, \( x \) is assigned the \( \text{crc} \) value of the \text{text\_line} variable.

**See Also**

cksum
curday (function)

Use curday to find out the current day of the month.

**Format**

\[ x = \text{curday} \]

**Comments**

curday returns the current day of the month. The returned value is always in the range of 1–31.

**Example 1**

\[ x = \text{curday} \]

In this example, \( x \) is set to the current day of the month.

**Example 2**

\[ \text{if curday} = 15 \text{ then gosub pay_bills} \]

In this example, control passes to the subroutine `pay_bills` if the current day is day 15.

**See Also**

`curmonth`, `curyear`, `date`
curdir (function)

Use curdir to check the name of the current directory.

Format

\[ x\$$ = \text{curdir}[(\text{string})] \]

Comments

curdir returns the current directory of the drive specified by string. If you do not specify string, curdir returns the directory of the current drive. curdir returns a null string if the specified drive is not available.

Example 1

\[ \text{where}_\text{we}_\text{are} = \text{curdir} \]

In this example, curdir stores the name of the current directory in the where\_we\_are variable.

Example 2

\[ \text{whats}_\text{on}_\text{a} = \text{curdir}("a:"\) \]

In this example, curdir stores the name of the current directory for drive A in the whats\_on\_a variable.

See Also

curdrive
curdrive (function)

Use `curdrive` to find out the current default drive.

**Format**

```
x$ = curdrive
```

**Comments**

`curdrive` returns a two-character string consisting of the letter of the current drive followed by a colon.

**Example 1**

```
what_we_are_on = curdrive
```

In this example, `curdrive` stores the letter of the current drive in the `what_we_are_on` variable.

**Example 2**

```
if curdrive > "C:" then ...
```

In this example, the macro takes some action if the letter of the current drive is greater than C (such as D, E, F, and so on).

**See Also**

`curdir`, `drive`
curhour (function)

Use curhour to get the current hour in a 24-hour format.

Format

\[ x = \text{curhour} \]

Comments

curhour returns an integer value containing the current hour, in the range of 0–23.

Example 1

\[ x = \text{curhour} \]

In this example, curhour sets the variable x to the number of the current hour.

Example 2

\[ \text{if curhour} = 23 \text{ then chain } "\text{CALLBBS}" \]

In this example, the macro chains to a macro called CALLBBS if curhour is set to 23.

See Also

curminute, cursecond
curminute (function)

Use curminute to get the current minute.

Format

\[ x = \text{curminute} \]

Comments

curminute returns an integer containing the current minute, in the range of 0–59.

Example 1

\[ x = \text{curminute} \]

In this example, \( x \) is set to the current minute.

Example 2

\[ \text{if curminute} = 30 \text{ then ...} \]

In this example, the macro takes some action if the current minute is equal to 30.

See Also

curhour, cursecond
curmonth (function)

Use curmonth to get the number of the current month.

Format

\[ x = \text{curmonth} \]

Comments

curmonth returns an integer value containing the current month, in the range of 1–12.

Example 1

\[ x = \text{curmonth} \]

In this example, \( x \) is set to the current month.

Example 2

\[ \text{if curmonth} = 12 \text{ then } \ldots \]

In this example, the macro takes some action if the current month is 12.

See Also

curday, curyear, date
cursecond (function)

Use cursecond to get the current second.

Format

\[ x = \text{cursecond} \]

Comments

\text{cursecond} \text{ returns an integer value containing the current second, in the range of 0–59.}

Example 1

\[ x = \text{cursecond} \]

In this example, \( x \) is set to the current second.

Example 2

\text{if cursecond = 30 then ...}

In this example, the macro takes some action if the current second is equal to 30.

See Also

\text{curhour, curminute}
curyear (function)

Use curyear to find out the current year.

Format

\[ x = \text{curyear} \]

Comments

curyear returns an integer value containing the current year.

Example 1

\[ x = \text{curyear} \]

In this example, \( x \) is set to the current year.

Example 2

\[ \text{if curyear = 2000 then } \ldots \]

In this example, the macro takes some action if the current year is 2000.

See Also

curday, curmonth, date
date (function)

Use date to return a date string.

Format

\[ x = \text{date}(\text{integer}) \]

Comments

If integer is not specified or has a value of 0, date returns a string containing the current system date.

The returned string uses the format specified in the Short Date Style in the Control Panel. To modify the format, click the Windows Start button, point to Settings, and click Control Panel. Double-click Regional Settings, click the Date tab, and click the desired item from the Short Date Style list box.

If integer is specified and has a value other than 0, it indicates the number of days that have elapsed since January 1, 1900, and date returns the date string for that day.

Example 1

\[ x = \text{date}(31354) \]

In this example, the macro sets \( x \) to 11/04/85.

See Also

curday, curmonth, curyear
definput (system variable)

Use definput to select a default file number for input.

Format

\[ \text{definput} = \text{filenum} \]

Comments

filenum must be an integer expression. definput lets you specify a default file number for all file input operations that follow the definput declaration. eof, eol, get, loc, read, read line, and seek, assume the file number specified by definput if no explicit file number is provided.

This variable is valid only for files opened in input or random mode.

See Also

eof, eol, get, loc, open, read, read line, seek
defoutput (system variable)

Use defoutput to select a default file number for output.

Format

defoutput = filenum

Comments

filenum must be an integer expression. defoutput lets you specify a default file number for all file output operations that follow the defoutput declaration. put, write, and write line assume the file number specified by defoutput if no explicit file number is provided.

This variable is valid only for files opened in output or random mode.

See Also

open, put, write, write line
**dehex (function)**

Use `dehex` to convert an `enhex` string back to its original format.

**Format**

\[ x$ = \text{dehex}(\text{string}) \]

**Comments**

`dehex` converts a string of ASCII characters in hexadecimal format back to a string of binary data.

Since each byte in `string` is a two-byte hexadecimal representation, the string returned by `dehex` is half as long as `string`.

Like `entext` and `detext`, `enhex` and `dehex` are complementary functions designed to permit the exchange of binary information over communications services that allow only 7-bit transfers; many of the electronic mail systems allow the transfer of only 7-bit ASCII information.

Binary data strings that have been converted with `enhex` require `dehex` to restore the 8-bit binary format.

**Example 1**

```
program_line = dehex(sendable)
```

In this example, `dehex` converts the ASCII hexadecimal string `sendable` to binary and returns the result in `program_line`.

**Example 2**

```
spread_sheet_line = dehex(nextline)
```

In this example, `dehex` returns the binary equivalent of `nextline` in `spread_sheet_line`.

**See Also**

`detext`, `enhex`, `entext`
delete (statement)

Use the delete statement to delete files from the disk.

**Format**

`delete [noask] "filename"`

**Comments**

Delete removes a file from the disk. *filename* must be a valid file name, which can contain a drive and directory. If *filename* contains wild cards, the user is asked to confirm the deletion of each file.

Use noask to suppress user intervention.

**Example 1**

`delete "script1.xws"`

In this example, the file SCRIPT1.XWS is deleted.

**Example 2**

`input f$ : delete f$`

In this example, the macro accepts the file name typed by the user and then deletes the file.
delete (function)

Use the delete function to remove characters from a string.

**Format**

\[ x$ = \text{delete}\left(string \ [, \ start \ [, \ length]\right) \]

**Comments**

delete returns string with length characters removed beginning at the character represented by start. If length is not specified, one character is removed. If start is omitted, the deletion starts at the first character position in string.

start must be in the range \(1 \leq start \leq \text{length}(string)\).

If start + length is greater than \(\text{length}(string)\), the leftmost \(start - 1\) bytes are returned.

**Example**

dog_name = delete("Fixxxdo", 3, 3)

In this example, the macro deletes three characters, starting at position 3, from the string "Fixxxdo". The result is Fido.
description (system variable)

Use description to read or set the description of the current session.

Format
description = string

Comments
description sets and reads the descriptive text associated with the current session. Only 40 characters are displayed. You can set the description to a null string ("").

Example
description = "Order Input"

In this example, the macro sets description to the indicated string.

See Also
name
destore (function)

Use destore to restore strings converted with the enstore function enstore function back to their original form.

Format

\[ x$ = \text{destore}(\text{string}) \]

Comments

destore converts strings of printable ASCII characters, which have been converted with enstore, back to their original embedded control character form.

Control characters in caret notation, such as `^G`, are converted back to control characters, in this case a Ctrl+g (bell) character. The vertical bar (|) is translated to a Ctrl+m (CR).

destore does not convert a caret preceded by a grave accent (`); however, the grave accent is discarded since it is no longer needed for protection; therefore, `^G becomes ^G.

You must have created string with enstore.

Example

\[ \text{line\_to\_show\_user} = \text{destore}(\text{password}) \]

In this example, destore converts the string password back to its original form and returns the result in line_to_show_user.

See Also

enstore
**detext (function)**

Use `detext` to convert an `entext` string back to its original form.

**Format**

\[
x\$ = \text{detext}(\text{string})
\]

**Comments**

This function works with the `entext` function to transfer 8-bit data over 7-bit networks. `entext` takes binary data and converts it to normal 7-bit ASCII characters (the result may even be readable); `detext` takes the `entext` data and converts it back to its original form.

You must have originally converted `string` with `entext`.

**Example**

\[
\text{convtd\_text} = \text{detext}(\text{ntxtd\_string})
\]

In this example, `detext` converts `ntxtd\_string` from 7-bit ASCII characters to 8-bit binary form and returns the result in `convtd\_text`.

**See Also**

`entext`
device (system variable)

Use device to read or set the connection tool for the current session.

Note: EXTRA! Enterprise for Accessory Manager sessions do not support this system variable.

Format

device = string

Comments

The connection tool used by T 27, UTS, and ALC sessions is ICSTOOL.

After you specify the connection tool with an assume statement, you can read or set variables that affect the configuration of the connection tool. For more information, refer to Chapter 7, “Connection, Terminal, and File Transfer Tools.”

Example

assume device "ICSTOOL"
print PathID

This example displays the name of the INFOConnect path type for the current session.

See Also

assume, protocol, terminal
dialogbox...endedialog (statements)

Use dialogbox...endedialog to create custom dialog boxes.

Format

dialogbox x,y,w,h [, caption]

[defpushbutton x, y, w, h, string [, options]]
[pushbutton x, y, w, h, string [, options]]
[ltext x, y, w, h, string]
[cctext x, y, w, h, string]
[rctext x, y, w, h, string]
[edittext x, y, w, h, init_text, ...
  str_result_var [, options]]
[radioobutton x, y, w, h, string, result_var ...
  [, options]]
[checkbox x, y, w, h, string, result_var ...
  [, options]]
[groupbox x, y, w, h, title]
[listbox x, y, w, h, comma_string, ...
  int_result_var [, options]]
[listbox x, y, w, h, string_array, ...
  int_result_var [, options]]

enddialog

Comments

This statement is useful for designing a user interface for your macros. Using dialogbox...endedialog, you can create dialog boxes that are easy to use and work like standard dialog boxes.

You must define all variables used in a dialog box before using the dialogbox...endedialog construct. The values assigned to variables for radiobutton, checkbox, and listbox are used to set the initial value of these dialog items. For radiobutton and checkbox, setting the Boolean variable result_var to true selects it; false does not. For listbox, setting the integer variable int_result_var determines which item in the list box is highlighted. The range is limited by the number of items in the list.

Unless otherwise specified, Accessory Manager defines the first letter of a button or prompt as an accelerator. You can define your own accelerator by placing an ampersand (&) in the string used for the text. The letter after the ampersand becomes the accelerator.
Chapter 6  CASL Language

The Dialog Box Items table describes the elements of the `dialogbox...enddialog` syntax. The Dialog Box Options table describes the options supported by those dialog box items that include `options` in their syntax.

### Dialog Box Items

<table>
<thead>
<tr>
<th>Item</th>

<tr>
<td><code>pushbutton</code></td>
<td>A button that the user can click (such as OK or Cancel)</td>
</tr>
<tr>
<td></td>
<td>For this dialog box item, the width should be the length of <code>string * 4</code> +</td>
</tr>
<tr>
<td></td>
<td>10. The height is usually 14.</td>
</tr>
<tr>
<td><code>ltext</code></td>
<td>Left-justified text within the dialog box</td>
</tr>
<tr>
<td></td>
<td>The width should be 4 times the length of <code>string</code>. The height is usually</td>
</tr>
<tr>
<td></td>
<td>8.</td>
</tr>
<tr>
<td><code>ctext</code></td>
<td>Centered text within the dialog box</td>
</tr>
<tr>
<td></td>
<td>The width should be 4 times the length of <code>string</code>. The height is usually</td>
</tr>
<tr>
<td></td>
<td>8.</td>
</tr>
</tbody>
</table>
### Dialog Box Items (Continued)

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rtext</td>
<td>Right-justified text within the dialog box</td>
</tr>
<tr>
<td></td>
<td>The width should be 4 times the length of <code>string</code>.</td>
</tr>
<tr>
<td></td>
<td>The height is usually 8.</td>
</tr>
<tr>
<td>edittext</td>
<td>A text box for user input</td>
</tr>
<tr>
<td></td>
<td>Precede <code>edittext</code> with <code>ltext</code>, <code>ctext</code>, or <code>rtext</code> to display a label for the text box.</td>
</tr>
<tr>
<td></td>
<td>The width of the text box should be at least four times the maximum length of the string the user may type.</td>
</tr>
<tr>
<td></td>
<td>The height is usually 12.</td>
</tr>
<tr>
<td><code>str_result_var</code></td>
<td>This returns the text typed in the edit box by the user</td>
</tr>
<tr>
<td>radiobutton</td>
<td>A round radio or option button that is chosen when clicked by the user</td>
</tr>
<tr>
<td></td>
<td>Radio buttons normally provide users with several mutually exclusive options. The first <code>radiobutton</code> in a group must have the <code>tabstop</code> group option set, or the arrow keys might not work properly in the dialog box.</td>
</tr>
<tr>
<td></td>
<td>The first dialog item after a group of <code>radiobutton</code> definitions must also have the <code>tabstop</code> group option so that the operating environment knows where one group ends and the next one begins.</td>
</tr>
<tr>
<td></td>
<td>The width of a <code>radiobutton</code> is generally the length of <code>(string * 4) + 10</code>. The height is generally 10.</td>
</tr>
<tr>
<td>result_var</td>
<td>This item is true if the radio button or check box is selected, false if not.</td>
</tr>
<tr>
<td></td>
<td>For radio buttons, you must examine <code>result_var</code> for each <code>radiobutton</code> until you find one that is set to true.</td>
</tr>
<tr>
<td></td>
<td>For check boxes, <code>result_var</code> is true or false depending on whether the check box was checked or not after the user exits the dialog box.</td>
</tr>
<tr>
<td>checkbox</td>
<td>A square box that is checked or cleared when the user clicks it</td>
</tr>
<tr>
<td></td>
<td>The width of a <code>checkbox</code> should be at least the length of <code>(string * 4) + 10</code>. The height is usually 12.</td>
</tr>
<tr>
<td>groupbox</td>
<td>A box for a group of dialog items yet to be defined</td>
</tr>
<tr>
<td></td>
<td>Dialog item definitions for this box should follow.</td>
</tr>
</tbody>
</table>

**Dialog Box Items (Continued)**

Chapter 6 CASL Language
Dialog Box Items (Continued)

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>title</td>
<td>The title of the group box</td>
</tr>
<tr>
<td></td>
<td>This appears in the upper border of the group box.</td>
</tr>
<tr>
<td>listbox</td>
<td>A list box</td>
</tr>
<tr>
<td></td>
<td>If you use comma_string with listbox, the list box displays the comma-delimited strings in comma_string. The width of the list box should be at least four times the length of the longest string in comma_string. The height should be eight times the number of items from comma_string that you want to display at one time. The height of the list box is limited by the height of the dialog box.</td>
</tr>
<tr>
<td>comma_string</td>
<td>The items to display in the list box, separated by commas</td>
</tr>
<tr>
<td>string_array</td>
<td>The array to display in the list box</td>

<td>The array must be single-dimensional with an alternative lower boundary of 1.</td>
</tr>
<tr>
<td>int_result_var</td>
<td>The number of the list box item selected</td>
</tr>
<tr>
<td></td>
<td>If no item was selected, zero is returned.</td>
</tr>
</tbody>
</table>
Chapter 6  CASL Language

Dialog Box Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tabstop</td>
<td>Marks a dialog item to which you can tab using the keyboard</td>
</tr>
<tr>
<td>tabstop group</td>
<td>Marks the beginning or end of a group of radio buttons</td>
</tr>
<tr>
<td></td>
<td>You normally press Tab to get to the first button in a group of radio buttons, then use the arrow keys to move from one button to the next. Pressing Tab again takes you to the next dialog item after the radio button group.</td>
</tr>
<tr>
<td>focus</td>
<td>Defines where to place the cursor within the dialog box</td>
</tr>
<tr>
<td></td>
<td>If this option is not used, the focus is set at the first tab stop in the dialog box.</td>
</tr>
<tr>
<td>secret</td>
<td>Specifies that placeholders should be displayed for the characters entered by the user.</td>
</tr>
<tr>
<td></td>
<td>This option is useful for entries such as passwords and applies only to edittext.</td>
</tr>
<tr>
<td>ok</td>
<td>Identifies the button to associate with Enter</td>
</tr>
<tr>
<td></td>
<td>This option applies only to defpushbutton or pushbutton.</td>
</tr>
<tr>
<td>cancel</td>
<td>Identifies the button to associate with Esc</td>
</tr>
<tr>
<td></td>
<td>This option applies only to defpushbutton or pushbutton.</td>
</tr>
</tbody>
</table>

When the user exits the dialog box, the variable choice is assigned the number of the button used to exit the dialog box. For example, if the first button is chosen, choice is set to 1; if the fourth button is selected, choice is set to 4. The macro can then check choice to take appropriate action. Note that no variables are updated if the user clicks Cancel.
Example 1
dialogbox 61, 20, 196, 76
  ltext 6, 4, 148, 8, "About calling " + ...
  "Administration directly ..."
  ltext 6, 24, 176, 8, "When setting up " + ...
  "Accessory Manager to call Administration"
  ltext 6, 36, 188, 8, "directly, you must " + ...
  "leave the NetID field blank."
  defpushbutton 80, 56, 36, 14, "OK", tabstop
enddialog

This example displays a simple dialog box that provides some information for the user. The user can read the text and click OK when ready to continue.

Example 2
string edit$
boolean check1, check2
boolean radio1, radio2
integer list1
string items[1:8]

label SampleDialog
  check1 = true -- true shows the check box selected
  check2 = true
  list1 = 3 -- a 3 highlights the 3rd
             -- item in the list
  radio1 = true -- true shows the radio
              -- button selected
  radio2 = false -- false shows that the radio
                   -- button is not selected
  items[1] = "Item1" -- array elements 1 through 8
  items[2] = "Item2"
  items[3] = "Item3"
  items[4] = "Item4"
  items[5] = "Item5"
  items[6] = "Item6"
  items[7] = "Item7"
  items[8] = "Item8"
This example produces a more complex dialog box that contains check boxes, a list box, text boxes, and radio buttons.

See Also

alert, choice, passchar
display (system variable)

Use display to enable or disable the display of incoming characters.

Format

\[
\text{display} = \text{option}
\]

Comments

option is one of the following:

<table>
<thead>
<tr>
<th>State</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>on</td>
<td>Incoming characters are displayed.</td>
</tr>
<tr>
<td>off</td>
<td>Incoming characters are not displayed.</td>
</tr>
</tbody>
</table>

Characters sent to the screen with the print statement are considered incoming characters and are not displayed if display is off.

display is active only while the macro that is using it is running.

Example

wait for "Password:"
display = off
reply password
display = on

In this example, the macro waits for the password prompt from the host. When the prompt is received, display is turned off, the contents of the system variable password are sent to the host, and display is turned back on.

See Also

print
do (statement)

Use do to compile and run a macro.

**Format**

do filename [, args]

**Comments**

Like the chain statement, the do statement invokes another macro and passes control to that macro. However, unlike the macro that uses the chain statement, the macro issuing the do statement does not terminate after it invokes the child macro. Instead, it waits until the other macro returns control.

Like chain, do compiles and runs a macro source file (.XWS) if there is no compiled version of the macro, or if the date of the source file is more current than the date of the compiled version. Otherwise, do runs the compiled version of the macro.

You do not have to include the macro extension, but you must include the drive and directory where the macro is located.

In the do statement, args represents an optional argument list that contains the individual arguments to be passed to the other macro. Individual arguments must be separated by commas.

When you use the do statement to invoke another macro, the macros can exchange variable information. To pass a variable between macros, declare the variable as public in the invoking macro and as external in the invoked macro. (For information about public and external variables, refer to Chapter 3, "Variables, Arrays, Procedures, and Functions."

For more information about invoking other macros, refer to Chapter 4, “Interacting with the Host, Users, and Other Macros.”

**Example 1**

do "C:\PROGRAM FILES\ATTACHMATE\INFOCN2K\ACCMGR32\SCRIPT2"

In this example, a macro called SCRIPT2 is invoked as a child macro.
Example 2

\[ \text{do } "\text{C:\PROGRAM FILES\ATTACHMATE\INFOCN2K\ACCMGR32\}\ SCRIPT2", "CSERVE"} \]

In this example, the argument CSERVE is passed to SCRIPT2.

See Also

arg, chain, compile
drive (statement)

Use drive to change the default disk drive.

Format

```
 drive string
```

Comments

`string` must be an expression representing a valid disk drive. The default drive for all subsequent file operations will be set to the new drive.

Example 1

```
 drive "A:"
```

In this example, the drive is changed to A.

Example 2

```
 drive dname$
```

In this example, the drive is changed to the value contained in the variable `dname$`.

See Also

curdrive
end (statement)

Use end to indicate the logical end of a macro.

**Format**

```
end
```

**Comments**

end marks the logical end of a macro. When an end statement is encountered, the following occurs:

- All variables associated with that macro are discarded.
- All files opened by the macro are closed.
- Execution of the macro is terminated.
- If the macro was invoked by a parent macro, execution continues in the parent macro.

Although it is a good programming practice to have an end statement at the physical end of the macro source code as well as at the logical end of the source code, CASL accepts the physical end of the macro as the logical end if no end statement is found.

**Example**

```
if not online then end
```

In this example, the macro ends if it is not online.

**See Also**

halt
enhex (function)

Use enhex to convert a string of binary data to a string of ASCII characters in hexadecimal format.

Format

\[ x$ = \text{enhex}(\text{string}) \]

Comments

enhex returns a string of ASCII characters that represent, in hexadecimal format, the data in string.

Since each byte in string is converted to a two-byte hexadecimal representation, the string returned by enhex is twice as long as string.

Like entext and detext, enhex and dehex are complementary functions designed to permit the exchange of binary information over communication services that allow only 7-bit transfers.

Binary data strings that have been converted with enhex require dehex to restore them to 8-bit binary format.

Example 1

sendable = enhex(program_line)

In this example, enhex converts the binary string program_line to a string of ASCII characters and returns the result in sendable.

Example 2

reply enhex(spread_sheet_line)

In this example, the macro sends the result of the enhex conversion to the host.

See Also

dehex, detext, entext
enstore (function)

Use enstore to convert strings that may have embedded control characters into strings of printable ASCII characters.

Format

\[ x\$ = \text{enstore}(\text{string}) \]

Comments

In general, control characters are changed to caret notation (that is, a Ctrl+g (bell) character is changed to ^G). When you use the resulting string in a string operation (such as a reply statement), the characters ^G are interpreted as Ctrl+g. The vertical bar ( | ) is used to represent Ctrl+m (CR).

enstore uses the grave accent( `) to protect any existing carets from later interpretation.

enstore is useful in macro file management of passwords and other strings that often contain embedded control characters.

Strings that have been converted with the enstore function can be returned to their original form with the destore function.

Example 1

```cpp
password = \text{enstore}("ALE" + \text{chr}(3))
```

In this example, the result of the enstore conversion is returned in password.

Example 2

```cpp
\text{reply enstore(line_input_by_user)}
```

In this example, the macro sends the result of the enstore conversion to the host.

See Also

destore
entext (function)

Use entext to convert a string of binary data to a string of printable ASCII characters.

Format

```plaintext
x$ = entext(string)
```

Like enhex and dehex, entext and detext are complementary functions designed to permit the exchange of binary information over communication services that allow only 7-bit transfers.

Binary data strings that have been converted to ASCII with entext require the detext function to restore them to 8-bit binary format. The algorithm used by entext changes three 8-bit characters to four printable characters.

Example 1

```plaintext
sendable = entext(program_line)
```

In this example, the ASCII equivalent of the binary string `program_line` is assigned to `sendable`.

Example 2

```plaintext
reply entext(spread_sheet_line)
```

In this example, `spread_sheet_line` is converted to ASCII characters and then sent to the host.

See Also
dehex, detext, enhex
environ (function)

Use `environ` to obtain the value of a DOS environment variable.

**Format**

```plaintext
x$ = environ(string)
```

**Comments**

`environ` returns the value of a specified operating system environment, such as the path.

`string` is not case-sensitive. A null string is returned if `string` is not found in the operating system environment.

**Example**

```plaintext
string dpath
dpath = environ("PATH")
```

In this example, the path setting is placed in the script's `dpath` variable.
eof (function)

Use eof to determine whether the end-of-file marker has been reached.

Format
\[
x = \text{eof}[(\text{filenum})]
\]

Comments
EOF returns true if the file specified in filenum is at the end of the file. It returns false until the last record has been read; then it returns true.

If filenum is not specified, the file number defaults to the definput system variable.

In random files, EOF returns true when the most recent get statement returns less than the requested number of bytes. get does not read past the end of the file.

In input (sequential) files, EOF returns true when the most recent read or read line statement reads the last record in the file. The contents of the last record of a file depend on the method used to create it. Some applications place a Ctrl+z (ASCII 26 decimal) character at the end of the file; other applications do not. Still other applications round out the file to a length evenly divisible by 128, either by writing multiple Ctrl+z characters or by writing a single Ctrl+z followed by whatever was in the rest of the output buffer on the previous write.

Example

\[
\text{string name}
\text{while not eof}
\quad \text{read name}
\quad \text{print name}
\text{wend}
\text{wend}
\text{end}
\]

This code fragment reads strings from an already open sequential file and prints them to the screen. When the end-of-file marker is reached, the while...wend loop is terminated, and the macro ends.

See Also
definput, get, read, seek
**eol (function)**

Use `eol` to determine if a carriage-return/line-feed character, indicating the end of a line, was part of the data read during the last `read` statement.

**Format**

```plaintext
x = eol([filenum])
```

**Comments**

`eol` returns `true` if the last `read` statement encountered a carriage-return/line-feed (CR/LF) character.

`filenum` is the file number assigned to the file when it was opened. If `filenum` is not specified, the file number defaults to the `definput` system variable.

Like `eof`, `eol` indicates the status of a data file following a `read` operation; however, `eol` works only on sequential input files, and reports whether the most recent `read` statement read the last field in the line (that is, encountered a CR/LF). Most applications use CR/LF to indicate the end of a line.

When reading comma-delimited ASCII files with `read` statements, use `eol` to ensure alignment of the file reading commands with the contents of the file, especially when the file was written using another application.

**Example**

```plaintext
string name
open input "names.dat" as 1
definput = 1
while not eof
  read name
  print name ;
  while not eol
    read name
    print " and " ; name ;
  wend
  print
wend
```
In this example, a file with a file number of 1 is opened for input. The two while...wend loops control the read operations. The outer loop is set so that the file is read until the end-of-file marker is reached. Within each read operation, the inner loop ensures that all of the data through the end-of-line character is read and printed.

See Also

definput, read
errclass (system variable)

Use errclass to check the type of the last error.

Format

\[ x = \text{errclass} \]

Comments

errclass contains an integer reflecting the type of error that last occurred. It is 0 if no error has occurred.

errclass is not cleared when you check it. It remains unchanged until another error occurs.

Example

\[
\text{trap on}\\
\text{send fname}\\
\text{trap off}\\
\text{if error then}\\
\text{case errclass of}\\
\hspace{1em}45: \text{goto file_tran_err}\\
\hspace{1em}26: \text{goto call_fail_err}\\
\hspace{1em}\text{default: goto other_err}\\
\text{endcase}
\]

This example shows how to test for such things as file transfer or call failure errors after a macro executes a file transfer command.

See Also

errno, error, trap
errno (system variable)

Use errno to check the specific type of the last error.

Format

\[ x = \text{errno} \]

Comments

errno contains an integer reflecting the error number, within the errclass, for the error that last occurred. It is 0 if no error has occurred.

errno is not cleared when you check it. It remains unchanged until a different error occurs.

Example

\begin{verbatim}
trap on
send fname
trap off
if error then E1 = errclass : E2 = errno
\end{verbatim}

In this example, error trapping is turned on, a file transfer is attempted, and trapping is turned off. If an error occurred, E1 is set to the value in errclass, and E2 is set to the value in errno.

See Also

errclass, error, trap
error (function)

Use `error` to check for the occurrence of an error.

**Format**

\[ x = \text{error} \]

**Comments**

`error` reports the occurrence of an error. It returns `true` if an error occurred and `false` if no error occurred.

`error` is reset each time it is tested. If you want to continue to trap errors throughout the execution of the macro, `error` must be cleared out (tested) after each error occurs.

When you use `error` with the `trap` compiler directive, you can direct program flow to an error handling routine.

`error` merely indicates that there has been an error. `errclass` and `errno` specify which error has occurred. `errclass` and `errno` are not cleared when tested.

**Note:** Fatal run-time errors cannot be trapped.

**Example**

```
trap on
compile "zark"
trap off
if error then print "Compile failed."
```

In this example, error trapping is turned on and the macro `zark` is compiled. Then error trapping is turned off. If an error occurred, the macro prints an error message.

**See Also**

`errclass`, `errno`, `trap`
exists (function)

Use exists to determine whether a file or subdirectory exists.

Format

\[ x = \text{exists}(\text{string}) \]

Comments

\textit{string} must be a legal file name or subdirectory name, and can contain drive specifiers, path names, and wildcard characters.

\textit{exists} returns \texttt{true} if the item specified in \textit{string} exists, and \texttt{false} if it does not. This function returns \texttt{true} if the directory exists, even if it’s empty.

Use \texttt{exists} only to check for files and subdirectories. It does not work for root directories.

Example 1

\begin{verbatim}
print \texttt{exists("ACCMGR32.EXE")}
\end{verbatim}

In this example, either \texttt{true} or \texttt{false} is displayed, depending on the existence of the file ACCMGR32.EXE.

Example 2

\begin{verbatim}
if \texttt{exists("C:\BIN") then}
    \texttt{print "BIN directory!"}
\end{verbatim}

In this example, a message is displayed if the directory BIN exists on the C drive.

Example 3

\begin{verbatim}
if \texttt{not exists(dat_file)} then \texttt{goto \texttt{dat_error}}
\end{verbatim}

In this example, the macro branches to the label \texttt{dat_error} if the \texttt{dat_file} does not exist.
exit (statement)

Use exit to exit from a procedure.

Format  
```plaintext
exit
```

Comments  
When an exit statement is encountered, the procedure returns control to the statement following the one that called it.

Example  
```plaintext
proc test takes integer x
    if x < 1 then exit
        print x; " seconds remaining."
    endproc
```

In this example, the procedure test is called with the argument x. If x is less than 1, the procedure returns control to the statement following the one that called it. Otherwise, a message is displayed, and then the procedure returns control when endproc is executed.

See Also  
chain, do, end, proc...endproc
false (constant)

Use false to set a Boolean variable to logical false.

Format

\[ x = \text{false} \]

Comments false is always logical false. Like its complement true, false exists as a way to set variables on and off. If false is converted to an integer, its value is 0.

Example

\begin{verbatim}
    done = false
    while not done
        ...
    wend
\end{verbatim}

In this example, the statements in the while...wend construct are repeated until done is true.

See Also

off, on, true
filefind (function)

Use filefind to check a file name.

Format

\[
x$ = \text{filefind}([\text{string} [, \text{integer}]])
\]

Comments

*string* must be a legal file specification that can include drive specifiers and path names as well as wildcard characters.

filefind returns the full path name of a file matching the pattern specified in *string*. If *string* is not used, filefind returns the name of the next file in the directory that fits the last file specification given as *string*. If no such file is found, filefind returns the null string.

If both *string* and *integer* are used, filefind returns the name of the first file in the directory whose name matches *string* and whose attribute bitmap equals *integer*. The bitmap returned is the total of the possible attributes shown in the following table:

<table>
<thead>
<tr>
<th>Hexadecimal</th>
<th>Decimal</th>
<th>Attribute Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x01</td>
<td>1</td>
<td>A read-only file.</td>
</tr>
<tr>
<td>0x02</td>
<td>2</td>
<td>A hidden file. The file is excluded from directory searches.</td>
</tr>
<tr>
<td>0x04</td>
<td>4</td>
<td>A system file. The file is excluded from directory searches.</td>
</tr>
<tr>
<td>0x08</td>
<td>8</td>
<td>The volume name of a disk.</td>
</tr>
</tbody>
</table>

*Note:* This is not supported.

<table>
<thead>
<tr>
<th>Hexadecimal</th>
<th>Decimal</th>
<th>Attribute Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x10</td>
<td>16</td>
<td>A directory.</td>
</tr>
<tr>
<td>0x20</td>
<td>32</td>
<td>An archive bit. This bit indicates the file has been changed since it was last backed up.</td>
</tr>
</tbody>
</table>
Example

```casl
x = filefind("*.\*")
while not null(x)
    print x
    x = filefind
wend
```

In this example, the macro displays a list of files in the current directory.
filesize (function)

Use filesize to check the size of a file.

Format

\[ x = \text{filesize}[(\text{filename})] \]

Comments

If \textit{filename} is used, \texttt{filesize} returns the size of the specified file. If \textit{filename} is not used, \texttt{filesize} returns the size of the file found by the most recent \texttt{filefind}.

\textit{Filename} must be a legal file specification that can contain drive specifiers and path names as well as wildcard characters.

Example 1

\texttt{progsiz}e = \texttt{filesize}("ACCMGR32.EXE")

In this example, the size of ACCMGR32.EXE is returned in \texttt{progsiz}e.

Example 2

\texttt{print filesize}

In this example, the macro displays the size of the file found by the most recent \texttt{filefind}.

See Also

\texttt{filefind}
fncheck (function)

Use fncheck to check the validity of a file name specification.

Format

\[ x = \text{fncheck}(\text{string}) \]

Comments

fncheck provides a quick way to parse file names. It returns a value indicating the presence or absence of various file name parts such as the drive letter, path, name, file type extension, and wildcards. For this to work properly, \textit{string} must be a legal file name.

The parts of the file name are determined by the punctuation found in the name. For example, if a colon is found, fncheck assumes that a drive letter is present. The following table lists the punctuation that is checked, the parts of the file name that are assumed as a result, and the values that are returned (hexadecimal and decimal).

<table>
<thead>
<tr>
<th>Punctuation</th>
<th>Part</th>
<th>Hexadecimal Value</th>
<th>Decimal Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Colon</td>
<td>Drive</td>
<td>0x01</td>
<td>1</td>
</tr>
<tr>
<td>Backslash</td>
<td>Directory</td>
<td>0x02</td>
<td>2</td>
</tr>
<tr>
<td>Period</td>
<td>Extension</td>
<td>0x04</td>
<td>4</td>
</tr>
<tr>
<td>Question mark</td>
<td>Wild card</td>
<td>0x08</td>
<td>8</td>
</tr>
<tr>
<td>Asterisk</td>
<td>Wild card</td>
<td>0x10</td>
<td>16</td>
</tr>
</tbody>
</table>

The values are added together for every part of a file name that is found.

Example

\begin{verbatim}
print fncheck(long_file_spec)
\end{verbatim}

In this example, the various parts of the file name \textit{long_file_spec} are displayed.

See Also

fnstrip
fnstrip (function)

Use fnstrip to return specified portions of a file name.

Format

\[
x$ = \text{fnstrip}(\text{string}, \text{specifier})
\]

Comments

fnstrip provides a quick way to parse file names, breaking them down into component parts like the drive letter, directory, and file name.

\text{string} must be a legal file name and can include a drive, directory, file name, and extension, as shown in the following example:

\text{C:\PROGRAM FILES\ATTACHMATE\INFOCN2K\ACCMGR32\ACCMGR32.EXE}

The parts of \text{string} that are returned are controlled by the value of \text{specifier}. Valid values for \text{specifier} are shown in the following table.

<table>
<thead>
<tr>
<th>Hexadecimal</th>
<th>Decimal</th>
<th>Portion Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00</td>
<td>0</td>
<td>The full file name</td>
</tr>
<tr>
<td>0x01</td>
<td>1</td>
<td>The directory, file name, and extension</td>
</tr>
<tr>
<td>0x02</td>
<td>2</td>
<td>The drive, file name, and extension</td>
</tr>
<tr>
<td>0x03</td>
<td>3</td>
<td>The file name and extension</td>
</tr>
<tr>
<td>0x04</td>
<td>4</td>
<td>The drive, directory, and file name (no extension)</td>
</tr>
<tr>
<td>0x05</td>
<td>5</td>
<td>The directory and file name (no extension)</td>
</tr>
<tr>
<td>0x06</td>
<td>6</td>
<td>The drive and file name (no extension)</td>
</tr>
<tr>
<td>0x07</td>
<td>7</td>
<td>The file name only (no extension)</td>
</tr>
</tbody>
</table>

Add 8 to \text{specifier} to return the string in all uppercase characters; add 16 (decimal) to return the string in all lowercase characters.
Example 1

print fnstrip(long_file_name, 3)

In this example, the macro displays the file name and extension.

Example 2

progsname = fnstrip(long_file_name, 7)

In this example, fnstrip returns only the file name (no extension).

Example 3

U_Case_ProgName = fnstrip("C:\PROGRAM FILES\ ... 
ACCMGR32\ACCMGR32.EXE", 15)

In this example, fnstrip returns the file name in uppercase characters.

See Also

fncheck
footer (system variable)

Use footer to define the footer to use when printing from Accessory Manager.

Format

```
footer = string
```

Comments

`string` can be any valid string expression. You can embed special characters in the string to print the date, time, and so on.

Example

```
footer = "Date: " + date
```

In this example, the word `Date:` and the current date are assigned to `footer`.

See Also

header
for...next (statements)

Use for...next to perform a series of statements a given number of times while changing a variable.

Format

```
for variable = startvalue to endvalue ...
  [step stepvalue]
  ...
  ...
next [variable]
```

Comments

- `variable` can be any integer or real variable. You do not have to declare the variable previously, but doing so is recommended. Do not change the value of `variable` within the for...next construct; this can produce erroneous results.

- `startvalue`, `endvalue`, and `stepvalue` can be any type of numeric expression. `startvalue` specifies the starting value for the counter, and `endvalue` specifies the ending value. (If you do not specify a `stepvalue`, 1 is assumed.)

The statements in the for...next construct are performed only under the following conditions:

- The `stepvalue` is greater than or equal to 0, and the `startvalue` is less than the `endvalue`.

- The `stepvalue` is less than zero, and the `startvalue` is greater than the `endvalue`.

The statements in the for...next construct are performed until the next statement is encountered. The value of `stepvalue` is then added to `variable`. If `stepvalue` is greater than or equal to 0, and if `variable` is not greater than `endvalue`, the statements are repeated. If `stepvalue` is less than 0, and if `variable` is not less than `endvalue`, the statements are repeated.

You can nest for...next constructs; that is, you can place one construct inside another one. If you use nested constructs, be sure to use different variables in each construct. In addition, make sure that a nested construct resides entirely within another construct.
Example 1

```plaintext
for i = 1 to 10
    print i
next i
```

In this example, the i variable is incremented by 1 each time the for...next construct is repeated. With each repetition, the value of i is displayed on the screen.

Example 2

```plaintext
for i = 10 to 1 step -1
    print i
next i
```

In this example, the i variable is decremented by 1 each time the for...next construct is repeated. With each repetition, the value of i is displayed on the screen.

Example 3

```plaintext
for i = 0 to 100 step 5
    print i
next
```

In this example, the i variable is incremented by 5 each time the for...next construct is repeated. With each repetition, the value of i is displayed on the screen.

Example 4

```plaintext
for i = 0 to 10
    print "Times table for "; i
    for j = 1 to 10
        print , i; " times "; j; " is: "; i * j
    next
    print
next
```

This is an example of nested for...next constructs. Multiplication tables for 1-1 through 10-10 are printed. Indentation is used here to show the relationship of the two constructs and for program readability.
freemem (function)

Use freemem to find out how much memory is available.

Format

\[ x = \text{freemem} \]

Comments

freemem returns the amount of memory that is available at the time the function is executed. The amount of available memory changes depending on the activity of other applications.

Example 1

\[ \text{print freemem} \]

In this example, the macro displays the amount of unused memory.

Example 2

\[ \text{if freemem} > 64k \text{ then } \ldots \]

In this example, the macro tests whether available memory exceeds 64 KB and then performs a certain action.
freetrack (function)

Use freetrack to return the lowest unused track number for the current session.

**Format**

```
   x = freetrack
```

**Comments**

freetrack returns the value of the next available track number. It lets you write general-purpose macros that do not require a specific track number. This is particularly valuable in a macro that might form part of several other macros.

You can have any number of track statements active at one time, limited only by available memory. freetrack returns zero if no track numbers are available.

Always store the results of the freetrack function in a variable, since the value of the function will change every time a new track is used.

**Example**

```
t1 = freetrack
track t1, space "system going down"
wait for key 27
if track(t1) then { bye : end }
```

In this example, the next available track number is assigned to t1. The track statement, using t1, watches for the specified string. Its occurrence is tested with the track function.

**See Also**

track (function), track (statement)
func...endfunc (function declaration)

Use func...endfunc to define and name a function.

Format

    func name ([{type} argument ...]
    [, [{type} argument]...]) returns type
    ...
    ...
    endfunc

Comments

A function is similar to a procedure, but it returns a value. You must declare the type of the return value within the function definition and specify a return value before returning.

The arguments are optional. If arguments are included, you must use the same number and type of arguments in both the function and the statement that calls the function. The arguments are assumed to be strings unless otherwise specified.

Any variable declared within a function is local to the function. The function can reference variables that are outside the function, but variables within the function cannot be referenced outside the function.

Functions can contain labels, and the labels can be the target of gosub...return and goto statements, but such activity must be wholly contained within the function. If you reference a label inside a function from outside the function, an error occurs.

You can nest functions at the execution level; that is, one function can call another. However, you must not nest functions at the definition level; one function definition cannot contain another function definition.

You can use forward declarations to declare functions whose definition occurs later in the macro. The syntax of a forward function declaration is the same as the first line of a function definition, with the addition of the forward keyword.

Forward declarations are useful if you want to place your functions near the end of your macro. A function must be declared before you can call it; the forward declaration provides the means to declare a function and later define what the function is to perform.
The following format is used for a forward declaration:

```casl
func name [(arglist)] returns type forward
```

You can use a similar approach to call functions in a Windows Dynamic Link Library (DLL). For more information, refer to “Calling DLL Functions” on page 77.

Functions can be in separate files. To include an external function in a macro, use the `include` compiler directive.

**Example 1**

```casl
func calc(integer x, integer y) returns integer
  if x < y then return x else return y
endfunc
```

In this example, the integers `x` and `y` are the function arguments. The values of `x` and `y` are passed to the function when it is called. The value returned by the function depends on the outcome of the `if...then...else` comparison. If `x` is less than `y`, `x` is the return value. If `x` is not less than `y`, `y` is the return value.

**Example 2**

```casl
func calc(integer x, integer y) returns ...
  integer forward
  return_value = calc(3, 8)
endfunc
```

In this example, the function `calc` is declared as a forward declaration. Then the function is called.

**Note:** For ease of programming, you do not have to supply the parameters in the actual function definition if you use a forward declaration. For instance, the preceding example can also be written as follows:

```casl
func calc(integer x, integer y) returns ...
  integer forward
  return_value = calc(3, 8)
endfunc
```

**See Also**

`include`, `proc...endproc`
**genlabels (compiler directive)**

Use *genlabels* to include or exclude label information in a compiled macro.

**Format**

```
  genlabels option
```

**Comments**

`option` is one of the following:

<table>
<thead>
<tr>
<th>Value</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>off</code></td>
<td>The macro compiler suppresses label information in the compiled macro. The resulting macro is usually smaller if you use this directive.</td>
</tr>
<tr>
<td><code>on</code></td>
<td>The macro compiler does not suppress label information in the compiled macro. The default for the directive is on.</td>
</tr>
</tbody>
</table>

**Note:** You cannot use the `goto @expression` statement if your macro contains the `genlabels off` compiler directive.

**Example**

```
genlabels off
```

In this example, *genlabels* is set to `off`.

**See Also**

`genlines`
genlines (compiler directive)

Use genlines to include or exclude line information in a compiled macro.

Format

    genlines option

Comments

    option is one of the following:

<table>
<thead>
<tr>
<th>Value</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>The macro compiler excludes line information from the compiled macro.</td>
</tr>
<tr>
<td>on</td>
<td>The macro compiler includes line information from the compiled macro. The default for the directive is on.</td>
</tr>
</tbody>
</table>

Example

    genlines off

    In this example, genlines is set to off.

See Also

    genlabels, trace
get (statement)

Use get to read characters from a random file.

**Format**

```casl
get [# filenum, ] integer, stringvar
```

**Comments**

get reads integer bytes from the random file identified by filenum and places the bytes read in the string variable stringvar. If filenum is not provided, the macro uses the value in definput.

If the end-of-file marker is reached during the read, stringvar might contain fewer than integer bytes, and might even be null.

Each get advances the file I/O pointer by integer positions or to the end-of-file marker, whichever comes first.

To use the get statement, you must open the file in random mode and have already declared stringvar.

**Example**

```casl
proc byte_check takes one_byte forward
string one_byte
get #fileno, 1, one_byte
while not eof(fileno)
    byte_check one_byte
    get #fileno, 1, one_byte
wend
```

This code fragment reads an already opened random file one byte at a time and calls a procedure to process the byte. This continues to happen until the end-of-file marker is reached.

**See Also**

definput, open, put, seek
go (statement)

Use go to establish communications with the host.

Format

```
go
```

Comments

go establishes a connection to the host and runs a session startup macro (if the session uses a session startup macro).

To determine whether the session uses a session startup macro, open the session, click Session Preferences from the Options menu, and click the CASL Macro tab. Any macro specified in the File Name text box is the session startup macro.

If the session is already connected to the host, go does nothing.

See Also

by, quit
Chapter 6  CASL Language

gosub...return (statements)

Use gosub to transfer program control temporarily to a subroutine. Use return to return control to the calling routine.

Format

gosub label
label label:

... ...
return

Comments

label must be the name of a subroutine label. The subroutine must end with a return statement.

Subroutines are helpful when you need to execute the same statements many times in a macro. You can use subroutines as many times as needed, and you can use the gosub statement in a subroutine to pass control to other subroutines. You can have up to eight nested subroutines.

When a gosub statement is encountered, the macro branches to label. When a return statement is encountered, program control returns to the statement after the one that called the subroutine. A subroutine can have more than one return statement.

Subroutines can appear anywhere in a macro, but it is a good programming practice to put all of your subroutines together, usually at the end of the macro.

Example

text = "Hello there."
gosub print_centered
end
label print_centered
l = length(text)
if l = 0 then return
print at ypos, (80/2)-(length(text)/2), text
return

This example shows a subroutine called print_centered that displays a string called text centered on the screen.

See Also

goto, label, pop
goto (statement)

Use goto to branch to a label or expression.

Format

\[
\text{goto label}
\]

or

\[
\text{goto @expression}
\]

Comments

label must be the name of a program label.

expression can be any string expression that represents a label in the macro. If you specify an expression, you must precede the expression with the “at” sign (@), which forces the expression to be evaluated at run time.

When a goto statement is encountered in a macro, the macro branches to label.

Note: If you use the goto @expression form of this statement, you cannot use the genlabels off compiler directive.

Example 1

goto main_menu

In this example, the macro branches to the label main_menu.

Example 2

goto @"handle_" + xvi_keyword

In this example, the macro branches to the specified expression.

See Also

gosub...return, label

**grab (statement)**

Use `grab` to send the contents of the session window to a file.

**Format**

`grab`

**Comments**

`grab` places the text in the session window into the file specified on the Print Screen Options dialog box.

For this statement to work, Print To File must be selected on the Print Screen Printer Settings dialog box. To do this, open a session, click Print Screen from the File menu, select Print To File, and click OK.

By default, the file name is the first five letters of the session name, followed by a letter for the month (January is A, February is B, and so forth), and the day of the month. The file extension is `.TXT`. For example, if the session name is TCPA_1 and the file is created on April 15, the file name is TCPA_D15.TXT. To change the file name, click Print Screen from the File menu, make sure Print To File is selected, click Options, clear Auto Name The File, and type the desired file name in the File Name text box. (You can also click Browse and select the desired file from a list of available files.)

**Example**

`grab`

**See Also**

capture, printer
halt (statement)

Use `halt` to stop macro execution.

**Format**

```
halt
```

**Comments**

When a halt statement is encountered, the macro stops immediately. If there is a related parent macro, it terminates also.

**Note:** To stop a running macro using Accessory Manager, click Stop CASL Macro from the Tools menu.

**Example**

```
if not online then halt
```

In this example, the macro stops executing if the session is not connected to the host.

**See Also**

`end`
header (system variable)

Use header to define the header to use when printing from Accessory Manager.

Format

header = string

Comments

string can be a any valid string expression. You can embed special characters in the string to print the date, time, and so on.

Example

header = "Printed using the " + description ... + " session."

In this example, the specified string is assigned to header.

See Also

footer
hex (function)

Use hex to convert an integer to a hexadecimal string.

Format

\[ x$ = \text{hex}(\text{integer}) \]

Comments

hex returns a string giving the hexadecimal representation of integer. If integer is between 0 and 65,535, the string is 4 characters long; otherwise, it is 8 characters long.

Example

print hex(32767)

In this example, the macro displays the hexadecimal equivalent of the integer 32,767.
hide (statement)

Use hide to minimize the session window.

Format

hide

Comments

This statement minimizes the session window. To minimize the Accessory Manager application window, use the minimize statement.

Example

hide

See Also

minimize, show, zoom
hideallquickpads (statement)

The hideallquickpads statement is supported only for backward compatibility. Refer to “unloadallquickpads (statement)” on page 330.
hidequickpad (statement)

The hidequickpad statement is supported only for backward compatibility. Refer to “unloadquickpad (statement)” on page 331.

## hms (function)

Use hms to return a string in a time format.

### Format

\[ x\$ = \text{hms}(\text{integer}[,\ \text{time\_type}]) \]

### Comments

hms converts integer to a string in any one of a number of time formats. integer is a number expressed in tenths of seconds, the same unit of time CASL uses for systime.

time\_type is a value that controls the format returned. It defaults to 0. The following table shows valid values for time\_type and the resulting time format:

<table>
<thead>
<tr>
<th>Hexadecimal</th>
<th>Decimal</th>
<th>300011 Format</th>
<th>101 Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00</td>
<td>0</td>
<td>8:20:01</td>
<td>0:00:10.1</td>
</tr>
<tr>
<td>0x01</td>
<td>1</td>
<td>8:20:01</td>
<td>10.1</td>
</tr>
<tr>
<td>0x02</td>
<td>2</td>
<td>8:20:01</td>
<td>0:00:10</td>
</tr>
<tr>
<td>0x03</td>
<td>3</td>
<td>8:20:01</td>
<td>10</td>
</tr>
<tr>
<td>0x04</td>
<td>4</td>
<td>8h20m1s</td>
<td>0h0m10.1s</td>
</tr>
<tr>
<td>0x05</td>
<td>5</td>
<td>8h20m1s</td>
<td>10.1s</td>
</tr>
<tr>
<td>0x06</td>
<td>6</td>
<td>8h20m1s</td>
<td>0h0m10s</td>
</tr>
<tr>
<td>0x07</td>
<td>7</td>
<td>8h20m1s</td>
<td>10s</td>
</tr>
</tbody>
</table>

### Example 1

```plaintext```
print hms(300011)
```

In this example, the macro displays the time.

### Example 2

```plaintext```
print hms(systime, 6)
```

In this example, the macro displays the number of ticks that Accessory Manager has been active in the 0h0m0s format.

### See Also

systime
**homedir (system variable)**

Use `homedir` to specify the drive and directory where Accessory Manager is installed.

**Format**

```
homedir
```

**Comments**

This is a read-only string variable. You can use it as an argument for another function or statement, or you can assign the value of `homedir` to a variable you create.

**Example 1**

```
chdir homedir
```

In this example, the macro changes the active directory to the Accessory Manager directory.

**Example 2**

```
run "winhelp.exe " + homedir + "\accmgr32.hlp"
```

In this example, the value of `homedir` is concatenated with the strings before and after it.

**Example 3**

```
mydir = homedir
```

In this example, the value of `homedir` is assigned to another variable. Because the new variable is not read-only, you can manipulate its value.

**See Also**

`chdir`, `curdir`
if...then...else (statements)

Use if...then...else to control program flow based on the value of an expression.

Format

```plaintext
if expression then
  statement group ...
[else statement group]
```

Comments

`expression` can be any type of numeric, string, or Boolean expression. It can also be a combination of numeric, string, and Boolean expressions connected with logical operators such as or, and, or not. `expression` must logically evaluate to either true or false. Integers do not have to be explicitly compared to 0, but strings must be compared to produce a true/false value.

For example, the following values evaluate logically to true:

1
1 = 1
1 = (2-1)
"X" = "X"
"X" = upcase("x")

The following conditions evaluate to false:

0
1 = 1
1 = 2
"X" = "Y"

`then` specifies the statement to perform if `expression` is true. `then` must appear on the same line as the `if` with which it is associated, as shown in the following example:

```plaintext
if done = true then
  print "Done!"
```

`else` specifies an optional statement to perform if `expression` is not true. Each `else` matches the most recent unresolved `if`.

Blank lines are not allowed within a `then...else` statement group. If you want to place blank lines in the `then...else` statement group to make the text more readable, use braces ({}) to enclose a series of statements.
Chapter 6  CASL Language

Example 1

label ask
    integer user_choice
    input user_choice
    if user_choice = 1 then
        print "Choice was 1." else
        if user_choice = 2 then
            print "Choice was 2." else goto ask
    
This example shows how to nest if statements in other if statements.

Example 2

if choice = 1 then print "That was 1." : alarm

This example shows how to specify multiple statements after an if statement. In this case, the print and alarm statements are performed only if choice equals 1.

Example 3

if choice=1 or choice=2 then print "One or two."
if online and (choice=1) then print "We're OK."
if x=1 or (x=2 and y<>9) then ...

These three examples show how to specify multiple conditions in an if...then statement. If the order in which the conditions are evaluated is important, use parentheses to force the order, as shown in the second and third examples.

Example 4

if track(1) then
    {
        bye
        wait 8 minutes
        print "Eight minutes have elapsed."
        end
    }

This example shows how to use braces to indicate a series of statements in an if...then construct. This can make if...then statements easier to read.

Example 5

if x then { if y then a } else b

This example shows how to use braces to denote the then with which an else should be associated.
include (compiler directive)

Use include to include an external file in your macro.

**Format**

`include "filename"`

**Comments**

`include` is a compile-time directive. It is normally used to include a source file of commonly used procedures and subroutines in a macro.

`filename` is required and must be the name of an existing file containing CASL language elements. If a file extension is omitted, .XWS is assumed.

`include` does not include the same file more than once during compilation.

**Example**

`include "myprocs"

In this example, the file MYPROCS.XWS is included in the macro.

**See Also**

chain, do, func...endfunc, proc...endproc
**inject (function)**

Use `inject` to return a string with some characters changed.

**Format**

```plaintext
x$ = inject("old_string", "repl_string" ...
        [, integer])
```

**Comments**

`inject` creates a new character string by replacing part of `old_string` with the characters in `repl_string`, beginning at the first character in `integer`. The resulting string is the same length as `old_string`.

`old_string` cannot be null. If `repl_string` is too long, it is truncated. `integer` must be in the range of `1 <= integer <= length of old_string`. If `integer` is omitted, the first character position is assumed.

**Example 1**

```plaintext
print inject("ACTMGR32.EXE", "C", 3)
```

In this example, the `T` in ACTMGR32.EXE is changed to a `C` and the result is displayed.

**Example 2**

```plaintext
dog_name = inject("xido", "F")
```

In this example, the `x` in `xido` is changed to an `F` and the result is stored in `dog_name`.

**See Also**

`insert`
inkey (function)

Use inkey to return the value of a keystroke.

**Format**

\[ x = \text{inkey} \]

**Comments**

inkey tests for keystrokes without stopping the macro to wait for a keystroke. This is useful if you want to check for a keystroke while performing other operations.

inkey returns the ASCII value (0–255 decimal) of the key pressed for the printable characters and a special value for the arrow keys, function keys, and special purpose keys (shown in the following table):

<table>
<thead>
<tr>
<th>Keyboard Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>F1–F10</td>
<td>1025–1034</td>
</tr>
<tr>
<td>Shift+F1–Shift+F10</td>
<td>1035–1044</td>
</tr>
<tr>
<td>Ctrl+F1–Ctrl+F10</td>
<td>1045–1054</td>
</tr>
<tr>
<td>Alt+F1–Alt+F10</td>
<td>1055–1064</td>
</tr>
<tr>
<td>Up Arrow</td>
<td>1281</td>
</tr>
<tr>
<td>Down Arrow</td>
<td>1282</td>
</tr>
<tr>
<td>Left Arrow</td>
<td>1283</td>
</tr>
<tr>
<td>Right Arrow</td>
<td>1284</td>
</tr>
<tr>
<td>Home</td>
<td>1285</td>
</tr>
<tr>
<td>End</td>
<td>1286</td>
</tr>
<tr>
<td>Page Up</td>
<td>1287</td>
</tr>
<tr>
<td>Page Down</td>
<td>1288</td>
</tr>
<tr>
<td>Insert</td>
<td>1297</td>
</tr>
<tr>
<td>Delete</td>
<td>1298</td>
</tr>
</tbody>
</table>

If no keystroke is waiting, inkey returns 0.

To clear the keyboard buffer before testing for a keystroke, use the following code:

```plaintext
while inkey : wend
```
If the key is important, store it in a variable, and then test the variable as shown in the following example:

```plaintext
x = inkey
if x <> 0 then ...
```

To make the user press Esc so the macro can continue, use the following code:

```plaintext
print at 0, 0, "Press Esc"
while inkey <> 27
wend
```

**Example 1**

```plaintext
if inkey then end
```

In this example, the macro ends if any key is pressed.

**Example 2**

```plaintext
while not eof(file1) and inkey <> 27 ...
```

In this example, a task is performed while the end-of-file marker has not been reached and Esc is not pressed.

**See Also**

input, stroke
input (statement)

Use input to accept input from the keyboard.

**Format**

```plaintext
input variable
```

**Comments**

`variable` is required, and can be any type of numeric or string variable. You can use the backspace key to edit input.

**Example**

```plaintext
input username
```

In this example, the data in `username` is accepted by the macro.

**See Also**
inkey
in script (function)

Use in script to check the labels in a macro.

Format

\[ x = \text{in script}(\text{expression}) \]

Comments

in script uses expression to check for the presence of a particular label in a macro. The value returned is true if expression is a label in the currently running macro, false if it is not. expression must be a string.

Note: The genlabels compiler directive must be on for this function to work properly.

Example

\[ \text{if in script}("HA_" + \text{user_input}) \text{ then} \ldots \]

In this example, the macro tests for the presence of the specified label.

See Also

enlabels, label
insert (function)

Use insert to return a string with some characters added.

Format

```plaintext
x$ = insert("old_string", "insert_string" ... [', integer])
```

Comments

insert creates a new character string by adding the characters in insert_string at the integer character position in old_string. The length of the resulting string is the combined length of old_string and insert_string.

old_string cannot be null. integer must be in the range of 1 <= integer <= length of old_string. If integer is omitted, the first character position is assumed.

Example 1

```plaintext
print insert("ACMGR32.EXE", "C", 2)
```

In this example, the macro inserts a C in the second position of ACMGR32.EXE and displays the result.

Example 2

```plaintext
dog_name = insert("ido", "F")
```

In this example, an F is inserted in the first position of ido and the result is stored in dog_name.

See Also

infect
**instr (function)**

Use `instr` to return the position of a substring within a string.

**Format**

```c
x = instr(string, sub_string [, integer])
```

**Comments**

`instr` reports the position of `sub_string` in `string` starting its search at character `integer`. If `integer` is omitted, the search begins at the first character. If `sub_string` is not found within `string`, 0 is returned.

`instr` can be used within a loop to detect the presence of a character that you want to change to another character. The following code fragment expands the tab characters, which some text editors automatically embed in lines of text.

```c
tb=chr(9)
t=instr(S, tb)
while t
    s=left(S, t-1) + pad("", 9-(t mod 8)) + ...
        mid(S, t+1)
    t=instr(S, tb)
wend
```

**Example 1**

```c
dog_place = instr("Here, Fido!", "Fido")
```

In this example, the substring `Fido` is found in position 7 of the string and the result is returned in `dog_place`.

**Example 2**

```c
if instr(fname, ".") = 0 then
    fname = fname + ".XWS"
```

In this example, the macro looks for the presence of the file extension for `fname`. If an extension delimiter (.) is not found, the extension is added.
intval (function)

Use `intval` to return the numeric value of a string.

**Format**

\[ x = \text{intval}(\text{string}) \]

**Comments**

`intval` returns an integer; it evaluates `string` for its numerical meaning and returns that meaning as the result. Leading white-space characters are ignored, and `string` is evaluated until a non-numeric character is encountered.

The macro language is quite flexible as to the number base (decimal or hexadecimal) used; end `string` with an `h` if it is hexadecimal, or `k` if it is decimal. (k is for kilobytes, so 1k = 1024).

A hexadecimal string cannot begin with an alphabetic character. If the string does not start with a numeric character, place a 0 at the beginning of the string.

The characters that have meaning to the `intval` function are 0 through 9, a through f, A through F, h, H, b, B, o, O, q, Q, k, K, and hyphen (-).

**Example**

\[ \text{num} = \text{intval}(\text{user\_input\_string}) \]

In this example, `user\_input\_string` is converted to an integer and returned in `num`.

**See Also**

`str`, `val`
jump (statement)

The jump statement, which is a synonym for the goto statement, is supported only for backward compatibility. For more information, refer to "goto (statement)" on page 211.
keys (system variable)

Use keys to read or set the keyboard map for the current session.

Format

keys = string

Comments

keys specifies the name of keyboard map for the current session. You have to specify the full DOS path (drive and directory) where the file is located, as well as the .EKM file extension.

Example 1

keys = "C:\PROGRAM FILES\ATTACHMATE\INFOCN2K\ACCMGR32\HSW.EKM"

In this example, the keyboard map for the session is changed to HSW.EKM.

Example 2

if keys = "C:\PROGRAM FILES\ATTACHMATE\INFOCN2K\ACCMGR32\HSW.EKM" then ...

In this example, the macro performs some action if the keyboard map for the current session is HSW.EKM.
**Chapter 6  CASL Language**

**label (statement)**

Use `label` to specify a named reference point in a macro file.

**Format**

```
label  labelname
```

**Comments**

`labelname` can be almost any printable characters. (Do not use reserved words or special characters as a label name.)

Labels are used in macros to provide a means of identifying a particular line in a program.

**Example**

```
label ask
input user_choice
if user_choice = 1 then
    print "Choice = 1."
return
```

In this example, the `label` statement defines the location of the `ask` subroutine.

**See Also**

`gosub...return, goto`
left (function)

Use left to return the left portion of a string.

Format

\[ x\$ = \text{left}(\text{string} [, \ \text{integer}]) \]

Comments

left returns the leftmost integer characters in string. If integer is not specified, the first character in string is returned. If integer is greater than the length of string, then string is returned.

Example 1

dog_name = left("Fidox", 4)

In this example, left returns Fido.

Example 2

print left(long_string, 78)

In this example, the first 78 characters of long_string are displayed.

Example 3

reply left(dat_rec, 24)

In this example, the first 24 characters of dat_rec are sent to the host.

See Also

mid, right, slice, strip, subst
length (function)

Use length to return the length of a string.

Format

\[ x = \text{length}(\text{string}) \]

Comments

Since CASL allows strings of up to 32,767 characters, length always returns integers in the range of \( 0 \leq \text{length of } \text{string} \leq 32767 \). length returns 0 if \text{string} is null.

Example 1

print length(dog_name), dog_name

In this example, the macro displays both the length of the string dog_name and the contents of the string.

Example 2

if length(txt_ln) then reply txt_ln
else reply "-"

In this example, the macro sends the contents of txt_ln to the host if txt_ln contains data. Otherwise, the macro sends a dash to the host.
loadquickpad (statement)

Use `loadquickpad` to open and display a QuickPad.

**Format**

```
loadquickpad string
```

**Comments**

This statement loads the QuickPad specified in `string`. You do not have to include the `.EQP` file extension.

**Example**

```
if online then
    loadquickpad "apad"
```

In this example, the QuickPad named APAD.EQP is loaded if the session is connected to a host.

**See Also**

`hideallquickpads`, `hidequickpad`, `showallquickpads`, `showquickpad`, `unloadallquickpads`, `unloadquickpad`
loc (function)

Use loc to return the position of the file pointer.

Format

\[ x = \text{loc}[(\text{filenum})] \]

Comments

loc returns the byte position of the next read or write in a random file.

If filenum is omitted, the default file number is assumed. You can set the default file number using the definput system variable.

This function is valid only for files opened in random mode.

Example 1

print loc(1)

In this example, the macro displays the location of the input/output pointer for file number 1.

Example 2

if loc(1) = 8k then print "Eight kilobytes read."

In this example, the macro prints the specified phrase if the file pointer is 8 KB into the file.

See Also

definput, open, seek
lowcase (function)

Use lowcase to convert a string to lowercase letters.

Format

\[ x\$ = \text{lowcase}(\text{string}) \]

Comments

lowcase converts only the letters A–Z to lowercase characters. Numerals, punctuation marks, and notational symbols are unaffected.

lowcase is useful for testing string equivalence since it makes the string case-insensitive.

Example 1

print "Can't find "; lowcase(fl_name)

In this example, the macro displays a phrase that contains a filename in lowercase letters.

Example 2

if lowcase(password) = "secret" then ...

In this example, the macro takes some action if the contents of password is secret.

See Also

upcase
lprint (statement)

Use lprint to send text to a printer.

Format

```
lprint [item] [{ , | ; } [item]] ... [ ; ]
```

Comments

`lprint` can take any item or list of items, including integers, strings, and quoted text, separated by semicolons or commas.

`item` can be either an expression to be printed, the `EOP` keyword, or the `EOJ` keyword. `EOP` indicates that printing should continue on another page. `EOJ` indicates the end of the print job; that is, the print spooler can now send the data to the printer. If your macro ends without executing an `lprint EOJ`, the macro processor executes one for you. If `item` is omitted, a blank line is printed.

If the items in the list are separated by semicolons, they are printed with no space between them. If they are separated by commas, they are printed at the next tab position.

A trailing semicolon at the end of the `lprint` statement causes the statement to be printed without a carriage return. This is useful when you want to print something immediately after the statement on the same line.

Example 1

```
lprint "This is being sent to the printer."
```

This example shows how to print a simple phrase.

Example 2

```
lprint "There's no carriage return after this."
```

This example shows how to suppress a carriage return.

Example 3

```
lprint "Current protocol is " ; protocol
```

This example shows how to print two phrases with no space between them.

Example 4

```
lprint "Hello, " , name$
```

This example shows how to print a phrase followed by an automatic tab to `name$`.

See Also

`print`
match (system variable)

Use match to check the string found during the last wait or watch statement.

**Format**

```
x$ = match
```

**Comments**

match returns the most recent string for which the macro was watching or waiting (up to 512 characters). For example, if the last wait or watch was looking for a keystroke, match returns the string value of the key pressed.

Use match only when the session is online.

**Example**

```casl
wait 1 minute for "Login", "ID", "Password"
case match of
    "Login": reply logon
    "ID": reply userid
    "Password": reply password
endcase
```

In this example, the macro waits up to one minute for the host to send a prompt. The macro then uses the case...endcase construct to determine what response to send to the host.

**See Also**

wait, watch...endwatch
**max (function)**

Use **max** to return the greater of two numbers.

**Format**

\[ x = \text{max}(\text{number1}, \text{number2}) \]

**Comments**

**max** compares two numbers and returns the greater of the two.

**Example**

```plaintext
integer a, b, c
a = 1
b = 2
c = \text{max}(a, b)
```

In this example, the macro declares three variables as integers and initializes two of them. Then it uses the **max** function to compare the integers `a` and `b` and returns the greater of the two in `c`. The result is `c = 2`.

**See Also**

**min**
maximize (statement)

Use `maximize` to enlarge the Accessory Manager application window to full screen size.

**Format**

```
maximize
```

**Comments**

`maximize` lets you maximize the Accessory Manager application window. To maximize a session window, use the `zoom` statement.

**Example**

```
maximize
```

**See Also**

`minize`, `move`, `restore`, `size`, `zoom`
mid (function)

Use mid to return the middle portion of a string.

Format

\[
x$ = \text{mid}(\text{string, start [, len]})
\]

Comments

mid returns the middle portion of string beginning at start, and returns len bytes. If len is omitted, or if start plus len is greater than the length of string, then the rest of the string is returned.

Example 1

dog_name = mid("Here, Fido, here boy!", 7, 4)

In this example, mid returns Fido in dog_name.

Example 2

if mid(fname, 2, 1) = ":" then dv = left(fname, 1)

In this example, dv is assigned the first character in fname if the second character in fname is a colon.

See Also

left, right, slice, strip, subst
min (function)

Use min to return the lesser of two numbers.

Format

\[ x = \text{min}(\text{number1}, \text{number2}) \]

Comments

min compares two numbers and returns the lesser of the two.

Example

integer a, b, c
a = 1
b = 2
c = min(a, b)

In this example, the macro declares three variables as integers and initializes two of them. Then it uses the min function to compare the integers a and b and returns the lesser of the two in c. The result is \( c = 1 \).

See Also

max
Chapter 6  CASL Language

**minimize (statement)**

Use minimize to reduce the Accessory Manager application window to an icon.

**Format**

minimize

**Comments**

minimize lets you minimize the Accessory Manager application window. To minimize a session window, use the hide statement.

**Example**

minimize

**See Also**

hide, maximize, move, restore, size
**mkdir (statement)**

Use `mkdir` to create a new subdirectory.

**Format**

```
mkdir directory
```

**Comments**

`directory` must be a string expression containing a valid directory name.

An error occurs if `directory` or a file with the same name as the one you specified for the directory already exists.

You can also use the abbreviation `md` for this statement.

**Example 1**

```
mkdir "C:\PROGRAM FILES\ATTACHMATE\INFOCN2K\ACCMGR32\FILE"
```

In this example, the macro creates a directory called `FILE` in the `C:\PROGRAM FILES\ATTACHMATE\INFOCN2K\ACCMGR32` directory.

**Example 2**

```
mkdir "FILE"
```

In this example, the macro creates a subdirectory called `FILE` under the current drive and directory.

**See Also**

`rmdir`
mkint (function)

Use mkint to convert strings to integers.

Format

\[
x = \text{mkint}(string)
\]

Comments

Use mkstr to convert 32-bit integers into 4-byte strings for compact storage in a file. When you read the file, use mkint to convert the strings to integers.

Example

get #1, 4, a_string : a_num = mkint(a_string)

In this example, the get statement reads four bytes of data from the file with file number #1 and stores the bytes in a_string. Then the mkint function converts the data in a_string to an integer and stores the result in a_num.

See Also

mkstr
mkstr (function)

Use `mkstr` to convert integers to strings for more compact file storage.

**Format**

```
x$ = mkstr(integer)
```

**Comments**

Use `mkstr` to convert 32-bit integers into 4-byte strings for compact storage in a file. When you read the file, use `mkint` to convert the strings to integers.

**Example 1**

```casl
print mkstr(65), mkstr(6565), mkint("A")
```

In this example, `mkstr` converts 65 and 6565 to strings, and `mkint` converts A to its equivalent integer value.

**Example 2**

```casl
put #1, mkstr(very_big_num)
```

In this example, the `mkstr` function converts `very_big_num` to a string, and the `put` statement writes the string to a file.

**See Also**

`mkint`
**move (statement)**

Use move to move the Accessory Manager application window to a new location on the screen.

**Format**

```
move x, y
```

**Comments**

This statement moves the upper-left corner of the Accessory Manager application window to the location specified by \( x \) and \( y \). \( x \) and \( y \) are the pixel coordinates of the columns and rows on the screen. The range of coordinates depends on the video hardware used.

**Example 1**

```
move 2, 30
```

This example shows how to move the application window to column 2, row 30.

**Example 2**

```
move x, y
```

In this example, the macro moves the application window to the location defined by the \( x \) and \( y \) variables.

**See Also**

maximize, minimize, restore, size
name (function)

Use name to get the name of the current session.

Format

x$ = name

Comments

name returns the name of the current session. The name of the session is the same as the .ADP file name and appears in the title bar of the session window.

Example

if name = "ansi" then go

In this example, if the name of the session is ANSI, the macro connects the session to the host.
**netid (system variable)**

Use *netid* to read or set a network identifier for the current session.

**Format**

```
netid = string
```

**Comments**

*netid* sets and reads the network address associated with the current session. The *netid* is limited to 40 characters.

**Note:** To set this parameter using Accessory Manager, click Session Preferences from the Options menu, click the CASL Macro tab, and type the desired string in the Network ID text box.

**Example**

```
netid = "CIS02"
```

In this example, *netid* is set to CIS02.
**new (statement)**

Use `new` to create or open a session.

**Format**

```
new [path\filename]
```

**Comments**

- `path` is the directory where the session profiles are stored. `filename` is the name of a session (.ADP file).

- If you omit the path and file name, the New Session Wizard runs, and you can create a new session.

- If you include the path and file name with no extension, CASL looks for a file named with the default session profile extension. (The default is .ADP.) If you have changed the default extension in Accessory Manager, CASL will look for a file named with this new extension.

- If you include the path and file name with an extension, CASL looks for a file named with the specified session profile extension.

If you include `path\filename` and you receive an error message indicating that the file could not be found, specify the drive and directory where the session is located and try again, or check Accessory Manager to determine if you are using the correct session profile extension.

**Note:** For information on changing session profile extensions, see the INFOConnect User's Reference.

**Example**

```
new "C:\PROGRAM FILES\ATTACHMATE\INFOCN2K\ACCMGR32\TCPA_1"
```
nextchar (function)

Use nextchar to return the character waiting at the communication device.

Format

\[ x\$ = \text{nextchar} \]

Comments

nextchar returns the character waiting at the communication device. If no character is waiting, nextchar returns a null string and processing continues.

The nextchar function clears the current character from the device. If you want to retain the character, store it in a variable and then test the variable.

Note that nextchar returns a string, while inkey returns an integer.

Example 1

/* The terminal assumes full duplex host. */
string nchar
integer kpress
while kpress <> 27
    nchar = nextchar
    if not null(nchar) then print nchar;
    kpress = inkey
    if kpress then reply chr(kpress);
wend

This example uses the nextchar and inkey functions to get characters from the device and the keyboard, respectively.

Example 2

nchr = nextchar : if null(nchr) then
gosub a_label

In this example, the macro tests whether or not the next character is a blank; if it is, control is passed to the subroutine a_label.

See Also

inkey, nextline
nextline (statement)

Use the nextline statement to get a line of characters from the communication port.

Format

```
nextline string [, time_expr [, maxsize]]
```

Comments

nextline accumulates the characters that arrive at the communication port (delimited by carriage returns) and returns them in the variable `string`.

If a carriage return has not been received since the last nextline, the program accumulates characters until one of the following occurs:

- A carriage return is encountered.
- The amount of time specified in `time_expr` is reached.
- `maxsize` characters have accumulated.

When one of these conditions is met, nextline returns the resulting string and processing continues. If no characters have been received, nextline returns a null string.

`time_expr` is the number of seconds to wait for the next carriage return or the next character. This number can be an integer or a real (floating point) number. If `time_expr` is reached between the receipt of characters, the characters accumulated to that point are returned and macro execution continues. You can use the `timeout` system variable to determine if the value in `time_expr` was exceeded. If `time_expr` is omitted, nextline accumulates characters until a carriage return is encountered or `maxsize` characters have accumulated.

`maxsize` is the number of bytes to accumulate before continuing if a carriage return is not encountered. The default (and maximum) is 255 bytes.

A line feed following a carriage return is ignored.
Example 1

nextline new_string

In this example, nextline waits for characters to come in from the port and stores them in the script's new_string variable.

Example 2

nextline big_string, 5.5, 100
if timeout then bye

In this example, nextline waits up to 5.5 seconds for as many as 100 characters or a carriage return. The nextline statement terminates if the specified conditions are not met within the specified 5.5-second time period. The timeout system variable is used to determine whether or not nextline timed out.

See Also

nextchar, nextline (function), timeout
nextline (function)

Use the nextline function to return a line of characters from the communication port.

Format

\[ x$ = \text{nextline}\left[\{\text{delay} [, \text{maxsize}]\}\right] \]

Comments

nextline looks for a carriage return and then returns the string of characters that have accumulated at the communication port.

If a carriage return has not been received since the last nextline, the characters accumulate until one of the following occurs:

■ A carriage return is encountered.
■ The amount of time specified in delay is reached.
■ maxsize characters have accumulated.

The resulting string is then returned and processing continues. If no characters have been received, a null string is returned.

delay is the number of seconds to wait for the next carriage return or the next character. This number can be an integer or a real (floating point) number. If delay is reached between the receipt of characters, the characters accumulated to that point are returned and the macro continues executing. By default, the nextline function waits indefinitely.

maxsize is the number of bytes to accumulate before continuing if a carriage return is not encountered. The default is 255 bytes.

A line feed following a carriage return is ignored.
Example 1

new_string = nextline

In this example, `nextline` waits for characters to come in from the port and stores them in the script's `new_string` variable.

Example 2

big_string = big_string + nextline(15, 1024)
if timeout then bye

In this example, `nextline` waits up to 15 seconds between characters for as many as 1,024 characters or a carriage return. The `nextline` function terminates if a carriage return is received, 1,024 characters are received, or 15 seconds elapse between characters. The characters are accumulated in the variable `big_string`.

See Also

`nextchar`, `nextline (statement)`, `timeout`
null (function)

Use null to determine if a string is null.

Format

\[ x = \text{null}(\text{string}) \]

Comments

null returns true if string is null; otherwise, it returns false.
 Nhi (Null strings have no length or contents.)

The following code fragments have equivalent results when testing the string a_string:

if null(a_string) then ...
if length(a_string) = 0 then ...

or

if length(a_string) then ...
if not null(a_string) then ...
if length(a_string) > 0 then ...

Example

print null("Fido"), null("")

In this example, the null function displays false for "Fido" and true for ".

See Also

length
octal (function)

Use `octal` to return a number as a string in octal format.

**Format**

\[ x\$ = \text{octal}(\text{integer}) \]

**Comments**

`octal` returns a string containing the octal (base 8) representation of `integer`. The string is 6 or 11 bytes long, depending on the value of `integer`. The following table shows possible `integer` ranges and the corresponding byte length.

<table>
<thead>
<tr>
<th>Integer Ranges</th>
<th>Byte Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>0–65,535</td>
<td>6</td>
</tr>
<tr>
<td>65,536–2,147,483,647</td>
<td>11</td>
</tr>
</tbody>
</table>

**Example**

`print octal(32767)`

This example show how to print the octal equivalent of 32,767 decimal.
off (constant)

Use off to set a variable to logical false.

Format

\[ x = \text{off} \]

Comments

off is always logical false. Like its complement on, off exists as a way to set variables.

Example

\[ \text{echo} = \text{off} \]

In this example, \text{echo} is set to off.

See Also

false, on, true
on (constant)

Use on to set a variable to logical true.

**Format**

\[ \text{x = on} \]

**Comments**

on is always logical true. Like its complement off, on exists as a way to set variables.

**Example**

```plaintext
echo = on
```

In this example, the variable `echo` is set to `on`.

**See Also**

false, off, true
online (function)

Use `online` to determine whether a connection is successful.

**Format**

\[ x = \text{online} \]

**Comments**

`online` returns `true` or `false`, depending on whether the session is online to another computer. Some macro statements and functions (such as `reply`) are inappropriate unless you are online when they are executed. You can use `online` to control program flow.

**Example 1**

```plaintext
while online ...
```

In this example, the macro performs some task while the session is connected to the host.

**Example 2**

```plaintext
if not online then new "C:\PROGRAM FILES\ATTACHMATE\INFOCN2K\ACCMGR32\TCPA_1"
```

In this example, if the session is not online, the macro opens the specified session.
ontime (function)

Use ontime to determine the number of ticks that the session has been online.

**Format**

\[ x = \text{ontime} \]

**Comments**

ontime returns the number of ticks that the session has been online. (One tick is one tenth of a second.) You can use ontime to call accounting routines, random number routines, and similar routines.

ontime is set to zero when a connection is established and stops counting when the session is disconnected.

To determine the number of ticks that Accessory Manager has been active, use the systime function.

**Example 1**

`print ontime`

In this example, the macro displays the value in ontime.

**Example 2**

`if ontime/600 > 30 then ...`

In this example, the macro tests the result of a mathematical computation and takes some action if the result is true.

**See Also**

online, systime
open (statement)

Use open to open a disk file.

Format

```
open mode filename as #filenum
```

Comments

Before a macro can read from or write to a file, the file must be
opened. open opens filename using filenum for the activities
allowed by mode.

mode can be any of the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>random</td>
<td>Allows input and output to the file at any location using seek, get, put, and loc. If the file does not exist, it is created.</td>
</tr>
<tr>
<td>input</td>
<td>Allows read-only sequential access of an existing file using read for comma-delimited ASCII records and read line for lines of text. If the file does not exist, a run-time error occurs.</td>
</tr>
<tr>
<td>output</td>
<td>Allows write-only sequential access to a newly created file using write for comma-delimited ASCII records and write line for lines of text. If the file exists, it is deleted and a new one is created.</td>
</tr>
<tr>
<td>append</td>
<td>Allows write-only sequential access to a file using write for comma-delimited ASCII records and write line for lines of text. If the file exists, the new data is appended to the end of it; otherwise, a new file is created.</td>
</tr>
</tbody>
</table>

filename can be any legal file name. Drive and directory names are allowed, but wild cards are not.

filenum must be in the range 1 <= filenum <= 8.

You can open a file in only one mode at a time.

Example

```
open random "PATCH.DAT" as #1
```

In this example, the macro opens PATCH.DAT in random mode with a file number of 1.

See Also

get, loc, put, read, read line, seek, write, write line
pack (function)

Use `pack` to return a condensed string.

**Format**

\[
x_\$ = \text{pack}(\text{string} [, \text{wild} [, \text{integer}]])
\]

**Comments**

`pack` returns `string` with duplicate occurrences of the characters in `wild` compressed according to the value of `integer`.

If `wild` is omitted, it defaults to a space.

`integer` specifies how consecutive characters in `string` are treated. The following `integer` values are valid:

<table>
<thead>
<tr>
<th>Value</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>All consecutive characters in <code>string</code> are compressed to a single occurrence of the first character. If <code>integer</code> is omitted, 0 is the default.</td>
</tr>
<tr>
<td>1</td>
<td>Only identical consecutive characters in <code>string</code> are compressed.</td>
</tr>
</tbody>
</table>

**Example 1**

`pack("aabcccdd", "abc", 0)`

In this example, `pack` returns `add` because `aabccc` is compressed to the first occurrence of the first character (a).

**Example 2**

`pack("aabcccdd", "abc", 1)`

In this example, `pack` returns `abcdd` because only identical consecutive characters are compressed.

**Example 3**

`pack("HELLO WORLD!", "L", 1)`

In this example, `pack` returns `HELO WORLD!` because the two Ls in `HELLO` are compressed to one L.
pad (function)

Use pad to return a string padded with spaces, zeros, or other characters.

Format

\[
x$ = \text{pad}(\text{orig\_str}, \text{len\_int}, [, \text{pad\_str} \ldots \ [, \text{where\_int}])
\]

Comments

Pad can expand, truncate, or center \text{orig\_str} to length \text{len\_int} by adding multiple occurrences of \text{pad\_str} on one or both sides as directed by \text{where\_int}.

Pad is essentially the opposite of the \text{strip} function, which removes certain characters from a string.

\text{orig\_str} can be any string.

\text{len\_int} is the number of characters that the returned string should be. If \text{len\_int} is shorter than the length of \text{orig\_str}, \text{orig\_str} is truncated to \text{len\_int} characters, with the truncation occurring on the right side of the string.

\text{pad\_str} can be any character. If \text{pad\_str} is omitted, it defaults to a space.

The value of \text{where\_int} indicates where to place the padding in the string (as shown in the following table.) If \text{where\_int} is omitted, it defaults to 1.

<table>
<thead>
<tr>
<th>This value</th>
<th>Places the pads here</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>On the right side</td>
</tr>
<tr>
<td>2</td>
<td>On the left side</td>
</tr>
<tr>
<td>3</td>
<td>On both sides, centering \text{orig_str} in a field \text{len_int} characters long</td>
</tr>
</tbody>
</table>
Chapter 6  CASL Language

Example 1

print pad("Hi", 6); pad("Hi", 6, "-"); ...
    pad("Hi", 4, "+", 2)

In this example, the first `pad` function adds four spaces to the right of `Hi` to expand the string to six characters. The second `pad` function adds four hyphens to the right of `Hi` to expand the string to six characters. The third `pad` function adds two plus signs to the left of `Hi` to expand the string to four characters.

Example

   cntrd_string = pad("Hello!", 78, "**", 3)

In this example, the `pad` function centers `Hello!` between two sets of 36 asterisks and returns the result in `cntrd_string`.

See Also

   strip
passchar (system variable)

Use `passchar` to specify the character to display in a text box on a dialog box created using `dialogbox...enddialog` and the `secret` option.

**Format**

```
passchar = char
```

**Comments**

By default, if you create a dialog box using `dialogbox...enddialog` and use `edittext` with the `secret` option, any text that you type in the resulting text box appears as asterisks on the screen.

Using `passchar`, you can specify a different character to display. For example, rather than displaying asterisks, you could display the plus sign.

**Example**

```
passchar = "+"
```

**See Also**

`dialogbox...enddialog`
password (system variable)

Use password to read or set a password string for the current session.

Format

password = string

Comments

password sets or reads the password associated with the current session. The password is limited to 40 characters.

Note: To set this parameter using Accessory Manager, click Session Preferences from the Options menu, click the CASL Macro tab, and type the desired string in the Password text box.

Example 1

password = "PRIVATE"

This example shows how to set the password.

Example 2

print password

This example shows how to print the password.

Example 3

reply password

This example shows how to send the password to the host.
perform (statement)

Use perform to call a procedure.

Format

perform procedurename [arglist]

Comments

perform is an alternate method of calling a procedure. It is like a combination of a forward declaration and a call. Use it to call procedures when they are located near the end of the macro.

procedurename is the name of the procedure to call.

arglist is a list of arguments that can be passed to the procedure. arglist must contain the same number and types of arguments in the same order as specified in the procedure declaration. Be sure to separate the arguments with commas.

Example

perform some_proc

In this example, the procedure identified by some_proc is called.

See Also

proc...endproc
pop (statement)

Use *pop* to remove a return address from the *gosub* return stack.

**Format**

`pop`

**Comments**

You can use *pop* in a subroutine to alter the flow of control. *pop* removes the top address from the *gosub* return stack so that a subsequent *return* statement returns control to the previous *gosub* rather than the calling *gosub*.

When you use the *pop* statement, the logic of your macro becomes somewhat convoluted. Therefore, use this statement only on those occasions where it cannot be avoided.

If the return stack is empty when the *pop* statement is encountered, an error occurs.

**Example**

`pop`

**See Also**

*gosub...return*
press (statement)

Use press to send a series of keystrokes to the terminal emulator.

Format

```
press [string [, string] ... ] [;]
```

Comments

press sends the string expression string to the emulator.

string can be plain text, special keystrokes (such as F1), or terminal keystrokes that vary, depending on the type of terminal that the session is emulating.

Be sure to enclose special keystrokes and terminal emulation keystrokes in angle brackets, such as <F1> and < Transmit >. You can also use the ASCII value for a keystroke, such as <8> to represent the backspace. (Additional keystroke values are listed in “inkey (function)” on page 225.) Characters that are not enclosed in angle brackets are treated as plain text.

To suppress a trailing carriage return, use a semicolon at the end of the statement. You usually need the semicolon with a T 27 session. Omitting the semicolon (and thus sending a carriage return after the keystroke) can cause problems. For example, if you're sending a communication keystroke, the carriage return generates a beep to indicate that the carriage return is being canceled. If you're sending a cursor movement keystroke, the keystroke is performed, but then the carriage return moves the cursor to the first column.

press differs from reply in that reply sends its output directly to the host, while press passes its output through the terminal emulator. reply does not honor any terminal keystrokes that are part of the terminal emulator; press does honor such keystrokes.

This statement is valid only when the session is online.

Example 1

```
keys_out = "<up><left>" : press keys_out ;
```

In this example, the Up Arrow and Left Arrow keystrokes are assigned to the variable keys_out, which is sent using the press statement.
Example 2

press "AM";

In this example, the macro sends the string AM without a trailing carriage return.

Example 3

press "<8>";

In this example, the macro sends a backspace.

See Also

reply
Chapter 6 CASL Language

print (statement)

Use print to display text in a session window.

Format

print [item] [{ , | ; } [item]] ... [ ; ]

Comments

item is one of the following:

{expression | at row, col}

The keyword at specifies a position in the session window; if it is omitted, printing begins at the current cursor position.

item can be any expression or list of expressions, including integers, strings, and quoted text, separated by semicolons or commas.

If the items in the list are separated by semicolons, they are printed with no space between them. If the items are separated by commas, they are printed at the next tab position. If no expression is included, a blank line is printed.

A trailing semicolon at the end of the print statement causes the item to be printed without a carriage return. This is useful when you want to print something else on the same line, or when printing on the last line of a session window.

print can be abbreviated as a question mark (?).

Example 1

print "The current protocol is " ; protocol

In this example, the macro prints the text The current protocol is followed by the name of the selected protocol.

Example 2

print "This is all printed on the ";
p

print "same line."

In this example, the macro prints the text on a single line.

Example 3

print date , time(-1)

In this example, the macro prints the date and the current time, with the time starting at the next tab stop.

See Also

grab, printer
printer (system variable)

Use printer to send screen output to a printer.

Format

printer = option

Comments

For the printer system variable, option is one of the following:

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>on</td>
<td>Accessory Manager sends the stream of characters coming from the communications port to the system printer.</td>
</tr>
<tr>
<td>off</td>
<td>Accessory Manager does not send the stream of characters to the system printer.</td>
</tr>
</tbody>
</table>

The settings specified on the Capture Options and Advanced Capture Options dialog boxes within Accessory Manager determine how the printing operates. To view these dialog boxes, make sure that Show Capture Dialog When Start Capture is selected on the Global Preferences dialog box. Then click Capture from the File menu, and click Options on the Capture Printer Settings dialog box.

Example

printer = off

This example shows how to turn printing off.

See Also

capture, grab
proc...endproc (procedure declaration)

Use proc...endproc to define and name a procedure.

Format

```
proc name [takes [type] argument
    [, [type] argument]...]
    ...
    ...
endproc
```

Comments

A procedure is a group of statements that can be predefined in a macro and later referred to by name.

`name` is the name given to the procedure. It must be unique within the macro.

`takes` is optional and introduces a list of arguments that are passed to the procedure.

`type` is optional and indicates the type of argument. The arguments are assumed to be strings unless otherwise specified.

`argument` is any argument to the procedure. Arguments are optional, and procedures can take a number of arguments. If arguments are included, you must use the same number and type of arguments in both the procedure and the statement that calls the procedure.

`endproc` ends the procedure. To leave a procedure before the endproc, use the exit statement to return control to the calling routine.

Any variable declared within a procedure is local to the procedure. The procedure can reference variables that are outside the procedure, but variables within the procedure cannot be referenced outside the procedure.

Procedures can contain labels, and the labels can be the target of `gosub...return` and `goto` statements, but such activity must be wholly contained within the procedure. If you reference a label inside a procedure from outside the procedure, an error occurs.

You can nest procedures at the execution level; that is, one procedure can call another. However, you must not nest procedures at the definition level; one procedure definition cannot contain another procedure definition.
You can use forward declarations to declare procedures whose definition occurs later in the macro. The syntax of a forward procedure declaration is the same as the first line of a procedure definition, with the addition of the forward keyword.

Forward declarations are useful if you want to place your procedures near the end of your macro. A procedure must be declared before you can call it. The forward declaration provides the means to declare a procedure and later define what the procedure is to perform.

The following format is used for a forward declaration:

```
proc name [takes arglist] forward
```

**Note:** You can also use the `perform` statement to call a procedure that is not yet declared.

You can use the `proc` statement to call a procedure in a Windows Dynamic Link Library (DLL). For more information, refer to "Calling DLL Functions" on page 77.

Procedures can be in separate files. To include an external procedure in a macro, use the `include` compiler directive.

**Example 1**

```
proc logon takes string username, ...  
    string logon_password
    watch for
        "Enter user ID:"       : reply username
        "Enter password:"     : reply logon_password
        key 27                 : exit
    endwatch
endproc
```

In this example, `username` and `logon_password` are the procedure arguments. The values of `username` and `logon_password` are passed to the procedure when it is called. The procedure watches for the appropriate prompts from the host and responds with one or the other of the arguments. If the Esc key is received, the procedure exits to the calling routine.
Chapter 6  CASL Language

Example 2  proc logon takes string username, string ...
  logon_password forward
logon "John", "secret"
proc logon takes string username, ...
  string logon_password
  watch for
    "Enter user ID:" : reply username
    "Enter password:" : reply logon_password
    key 27 : exit
  endwatch
endproc

In this example, the procedure logon is declared as a forward declaration. Then it is called.

Note: For ease of programming, you do not have to supply the parameters in the actual procedure definition if you use a forward declaration. For instance, the foregoing example can also be written as follows:

proc logon takes string username, ...
  string logon_password forward
logon "John", "secret"
proc logon
  watch for
    "Enter user ID:" : reply username
    "Enter password:" : reply logon_password
    key 27: exit
  endwatch
endproc

See Also  func...endfunc, exit, include, gosub...return, goto, perform
**protocol (system variable)**

Use `protocol` to set or read the file transfer protocol.

**Note:** EXTRA! Enterprise for Accessory Manager sessions do not support this system variable.

**Format**

```
protocol = string
```

**Comments**

`protocol` checks or changes the protocol to use for file transfers.

`string` can be one of the file transfer protocols listed in the following table:

<table>
<thead>
<tr>
<th>This protocol name</th>
<th>Loads this file transfer protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>CANDE</td>
<td>CANDE</td>
</tr>
<tr>
<td>OS2200</td>
<td>OS2200</td>
</tr>
<tr>
<td>MAPPER</td>
<td>MAPPER®</td>
</tr>
<tr>
<td>NOFT</td>
<td>No file transfer protocol</td>
</tr>
</tbody>
</table>

**Note:** You cannot change to a file transfer protocol that is not supported by the session’s terminal type. For example, you can change from CANDE to NOFT, but you cannot change from CANDE to OS2200, since the former is designed for use with T 27, and the latter for use with UTS. Any changes made using this command are written to the session’s .ADP file.

For more information about file transfer protocols, refer to Chapter 7, “Connection, Terminal, and File Transfer Tools.”

**Example 1**

```casa
assume protocol "CANDE"
protocol = "CANDE"
```

In this example, the CANDE file transfer protocol is loaded.

**Example 2**

```casa
print protocol
```

In this example, the macro prints the current protocol selection.

**See Also**

`assume`, `device`, `terminal`
put (statement)

Use `put` to write characters to a random file.

**Format**

```plaintext
put [#filenum, ] string
```

**Comments**

`put` writes `string` to the random file specified by `filenum`. The length of `string` is the number of bytes written to the file.

`filenum` must be an open random file number. If `filenum` is omitted, the file number stored in the variable `defoutput` is assumed.

Each `put` advances the file I/O pointer by the number of positions in `string`. The `put` statement does not pad `string` to a particular length. (To pad the string, you must use the `pad` function.) The `put` statement also does not add quotation marks, carriage returns, or end-of-file markers.

If the end-of-file marker is reached during the write, the file is extended.

**Example 1**

```plaintext
put #1, some_string
```

In this example, the macro writes `some_string` to a file with a file number of 1.

**Example 2**

```plaintext
put #fileno1, pad(rec, rec_len)
```

In this example, `rec` is padded on the right with spaces to expand the string to `rec_len` characters, and then `rec` is written to the file designated by `fileno1`.

**See Also**

`defoutput`, `open`, `pad`, `seek`
Chapter 6  CASL Language

quit (statement)

Use quit to close a session window.

| Note: EXTRA! Enterprise for Accessory Manager sessions do not support this statement. |

Format  
quit

Comments  
quit closes a session window. Unlike the terminate statement, quit does not close Accessory Manager, even if you use quit to end the last or only active session.

Example  
quit

See Also  
terminate
quote (function)

Use quote to return a string enclosed in quotation marks.

Format

\[ x$ = \text{quote}(\text{string}) \]

Comments

quote analyzes string and returns it enclosed in quotation marks to make it compatible with the type of comma-delimited ASCII sequential file input/output used by many applications.

quote encloses any string that contains a comma in double (") quotation marks.

string cannot contain both single and double quotation marks.

Example

print quote("Hello, world!")

In this example, the phrase "Hello, world!" is enclosed in double quotation marks when it is displayed on the screen.
Chapter 6 CASL Language

read (statement)

Use read to read lines containing comma-delimited fields of ASCII data in a sequential file.

Format

read [#filenum, ] string_var_list

Comments

The read statement operates only on files opened in input mode.

`filenum` must be an open input file number. If `filenum` is omitted, the default input file number stored in `definput` is assumed.

The read statement reads lines containing comma-delimited fields of ASCII data. Each `read` puts fields into the members of `string_var_list` until either all of the members have had values assigned or the end-of-file marker is reached. Quotation marks are automatically stripped. When an end-of-line marker is reached, it is treated as a comma (delimiter).

To use the `read` statement, you must have previously defined all members of `string_var_list`.

Example

read #fileno, alpha, beta, gamma

In this example, the `read` statement uses file number `#fileno` to read fields of ASCII data into the variables `alpha`, `beta`, and `gamma`.

See Also

definput, open, read line
**read line (statement)**

Use `read line` to read lines of text from a sequential file.

**Format**

`read line [#filenum, ] string_var`

**Comments**

The `read line` statement operates only on files opened in input mode.

`filenum` must be an open input file number. If `filenum` is omitted, the default input file number stored in `definput` is assumed.

The `read line` statement reads lines of text from files. Each `read line` puts in `string_var` all the text read, up to the next carriage-return/line-feed (CR/LF) character or a maximum of 255 characters, whichever comes first. If the end-of-file marker has already been reached, `string_var` is null.

To use the `read line` statement, you must have previously declared `string_var`.

**Example**

```plaintext
read line #1, some_text
```

In this example, the `read line` statement uses the file number #1 to read a line of text into the variable `some_text`.

**See Also**

`definput`, `open`, `read`
receive (statement)

Use `receive` to receive a file from the host.

**Format**

```
receive filename
```

**Comments**

`receive` tells Accessory Manager to download a file from the host. 
`filename` is the name of the file to download.

The way `receive` works depends on the file transfer protocol you use. For example, some protocols automatically request information from the host while other protocols require user intervention to request data.

An error occurs if the statement is executed while the session is offline.

For 3270, you must indicate the source and destination for the file.

**Example 1**

```
receive fname
```

In this example, `receive` downloads the file with the name assigned to the `fname` variable.

**Example 2**

```
receive "SALES"
```

In this example, `receive` downloads a file named SALES.

**Example 3**

```
receive test.txt C:\test\test.txt
```

In this example, `receive` downloads a file named TEXT.TXT to the test folder on the C drive. Note the single space separating the source and the destination for the file.

**See Also**

`online`, `send`
rename (statement)

Use `rename` to rename a file.

**Format**

```
rename [some] oldname, newname
```

**Comments**

This statement renames a file. `oldname` must be the name of an existing file and can contain wildcards. If `some` is included, the user is prompted for verification before each file is renamed.

**Example 1**

```
rename "TEST.XWS", "MAIL.XWS"
```

In this example, the macro renames the existing file `TEST.XWS` to `MAIL.XWS`.

**Example 2**

```
rename FNAME1, FNAME2
```

In this example, the macro renames the file in the `FNAME1` variable to the name in the `FNAME2` variable.
repeat...until (statements)

Use repeat...until to repeat a statement or series of statements until a given condition becomes true.

Format

repeat  
...  
...  
...  
until expression

Comments

repeat lets you repeat a group of statements until some condition occurs. until specifies the condition that ends the repeat condition. expression can be any Boolean, numeric, or string expression.

The loop is executed once before expression is checked. If expression is false, the loop repeats until expression is true.

The repeat...until construct is a good alternative to the while...wend construct in those instances where a loop must be executed at least once before its terminating condition is tested.

Example 1

x = 0  
repeat  
  x = x + 1  
  print x  
until x = 100

In this example, the macro prints numbers from 1 to 100.

Example 2

string guess  
print "Guess how to get out of here:"  
repeat  
  input guess  
until guess = "Good Bye!"

This example shows how a macro can prompt the user to type a string and repeat the prompt until the correct string (Good Bye!) is typed.

See Also

while...wend
reply (statement)

Use reply to send a string of text to the communication device.

Format

```
reply [string [, string] ... ] [ ; ]
```

Comments

reply sends one or more strings of text directly to the communication device. string is a string expression containing the text to be transmitted.

reply sends a carriage return after it sends string. To suppress this, include a semicolon at the end of the statement. If you use reply without a string, it sends only a carriage return. You usually need the semicolon with T 27 sessions.

Use this statement only when the session is online.

For related information, see the press statement.

Example 1

```
reply "Hello!"
```

In this example, the macro sends Hello!

Example 2

```
reply userid + " " + password
```

```
or
```

```
reply userid, " ", password
```

```
or
```

```
reply userid;
reply " ";
reply password
```

In this example, the macro sends the user ID, a space, and the password.

Example 3

```
reply chr(3);
```

In this example, the macro sends a ^C to the host.

See Also

press
request (statement)

The request statement, which is a synonym for the receive statement, is supported only for backward compatibility. Refer to “receive (statement)” on page 286.
restore (statement)

Use `restore` to restore the Accessory Manager application window to its previous size.

**Format**

```
restore
```

**Comments**

The `restore` statement restores the Accessory Manager application window to the size it was before it was maximized or minimized.

This statement applies only to the Accessory Manager application window. To restore a session window, use the `show` statement.

**Example**

```
restore
```

**See Also**

`maximize`, `minimize`, `move`, `show`, `size`
return (statement)

Use return to exit a function or to return from a subroutine.

**Format**

\[
\text{return \ [expression]} \nonumber
\]

**Comments**

When the return statement is used to exit a function, it returns a value. expression is the return value.

When return is used in a subroutine, the statement does not return a value.

**Example 1**

\[
\text{func calc\_largest (integer num1, \ldots)} \\
\quad \text{integer num2) returns integer} \\
\quad \text{if num1 > num2 then return num1} \\
\quad \text{else return num2} \\
\text{endfunc} 
onumber
\]

In this example, the function compares two numbers to determine which is larger and returns that number.

**Example 2**

\[
\text{integer i} \\
\text{gosub count\_to\_10} \\
\text{end} \\
\text{label count\_to\_10} \\
\quad \text{for i = 1 to 10} \\
\quad \quad \text{print i} \\
\quad \text{next} \\
\text{return} 
onumber
\]

In this example, the macro calls a subroutine to display the numbers 1 to 10. Note that the return statement does not return a value in this example.

**See Also**

func...endfunc, gosub...return
right (function)

Use right to return the right portion of a string.

Format

\[
x$ = \text{right}\left(\text{string}, \text{integer}\right)
\]

Comments

right returns the rightmost integer characters in string. If integer is not specified, the last character in string is returned. If integer is greater than the length of string, string is returned.

Example 1

dog_name = right("Hey, Fido", 4)
In this example, right returns Fido in dog_name.

Example 2

print right(long_string, 78)
In this example, the last 78 characters in long_string are printed on the screen.

See Also

left, mid, slice, strip, subst
rmdir (statement)

Use `rmdir` to remove a subdirectory.

**Format**

```
rmdir directory
```

**Comments**

`directory` must be a string expression containing a valid directory name. If the directory name exists and contains no files or subdirectories, it is removed. If it does not exist or if it contains files or subdirectories, an error occurs.

You can also use the abbreviation `rd` for this statement.

**Example 1**

```
rmdir "C:\PROGRAM FILES\ATTACHMATE\INFOCN2K\ACCMGR32\TMP"
```

In this example, the `rmdir` statement removes the TMP subdirectory.

**Example 2**

```
rmdir some_dirname
```

In this example, `rmdir` removes the directory contained in `some_dirname`.

**See Also**

`mkdir`
run (statement)

Use run to run another application.

Format

run "filename"

Comments

This statement starts another application. filename is the name of the executable file.

If the file does not reside in a directory included in the PATH statement of your AUTOEXEC.BAT file, you must specify the drive and directory where the file is located.

Example 1

run "NOTEPAD.EXE"

In this example, the macro runs Notepad. (In this case, the drive and directory are included in the PATH statement in the AUTOEXEC.BAT file, and are therefore not required in the run statement.)

Example 2

run "D:\APPS\CLOCK.EXE"

In this example, the macro runs CLOCK.EXE, which is located in the APPS directory on drive D. In this case, the drive and directory are included in the run statement, since they are not included in the PATH statement in the AUTOEXEC.BAT file.
save (statement)

Use save to save a session.

Format

save ["name"]

Comments

name is optional. If name is included, it must be a valid file name, and the session is saved using that name. You do not have to include the .ADP file extension. If name is not included, the session is saved under its current name.

Example 1

save

In this example, the script saves the session using its current name.

Example 2

save "Source"

In this example, the script saves the session as SOURCE.ADP.
script (system variable)

Use script to specify the name of the session start-up macro.

**Format**

```plaintext
script = filename
```

**Comments**

script specifies the name of the macro to run each time you open the session. filename must be a valid file name; you do not have to include the .XWC file extension.

**Example 1**

```plaintext
script = "LOGON"
```

In this example, the session start-up macro is set to LOGON.XWC.

**Example 2**

```plaintext
if script = "LOGON" then ...
```

In this example, some action is taken if the start-up macro for the session is named LOGON.XWC.

**See Also**

startup
scriptdesc (compiler directive)

Use scriptdesc to specify a description for a macro.

**Format**

```
scriptdesc string
```

**Comments**

`scriptdesc` defines descriptive text for a macro. `string` can be up to 40 characters in length.

**Example**

```
scriptdesc "Login macro for MARC"
```

In this example, `scriptdesc` is set to the specified string.
secno (function)

Use secno to return the number of seconds since midnight.

Format

\[ x = \text{secno}((hh, \ mm, \ ss)) \]

Comments

secno returns the number of seconds since midnight.
You can get the number of seconds that have elapsed since midnight for any given time by passing the hours, minutes, and seconds of that time as \( hh, mm, \) and \( ss \) (24-hour format).

Example 1

\begin{verbatim}
print secno
\end{verbatim}

In this example, the number of elapsed seconds since midnight are printed on the screen.

Example 2

\begin{verbatim}
print secno(14, 2, 31)
\end{verbatim}

In this example the macro prints the number of elapsed seconds since midnight for the time 2:02:31 P.M.
Chapter 6  CASL Language

seek (statement)

Use seek to move a random file input/output pointer.

Format

seek [#filenum, ] integer

Comments

seek moves a random file input/output pointer to character position integer. The next get or put action commences at that point. (The first byte in a file is character position 0.)

filenum must be an open input file number. If filenum is omitted, the default input file number stored in definput is assumed.

integer is the number of bytes from the beginning of the file, not the current location. (See the loc function earlier in this chapter for more information.)

seek does not move the pointer beyond the end-of-file marker.

Each get or put advances the input/output pointer by the number of bytes read or written. If the records in a random file are of fixed length and each get reads one record, reading the file backwards requires that after each get you must seek backwards two records.

You must open the file in random mode to use this statement.

Examples

seek #1, 0

In this example, the pointer is positioned at the beginning of the file.

seek #1, rec_len * rec_num

In this example, seek moves the I/O pointer to the position that results from multiplying the record length by the record number.

See Also

get, loc, open, put
send (statement)

Use send to transfer a file to a host.

Format

send filename

Comments

send initiates a file transfer to the host. filename is the name of the file to send, and can be a full path name.

The operation of this command depends on the file transfer protocol in use. For example, some file transfer protocols display a dialog box when you initiate a file transfer; others do not.

This statement is valid only when the session is online.

For 3270, you must indicate the source and destination for the file.

Example 1

send "B:\INVOICE"

In this example, the send statement sends the file INVOICE from drive B on the PC to the host.

Example 2

send some_fname

In this example, the send statement sends the file assigned to some_fname.

Example 3

send C:\test\test.txt test.txt

In this example, the send statement sends the file TEXT.TXT from the test folder on the C drive. Note the single space separating the source and the destination for the file.

See Also

receive
sendbreak (statement)

Use sendbreak to send a break signal to the host.

Note: EXTRA! Enterprise for Accessory Manager sessions do not support this statement.

Format

sendbreak

Comments

This statement sends a break signal to the host. Break signals are often interpreted by host systems as a cancel signal, and they usually stop some action.

This statement is valid only when a session is connected to a host.

Example

sendbreak
session (function)

Use `session` to find out the current session number.

**Format**

```plaintext
x = session
```

**Comments**

The `session` function returns the session number of the current session, which may or may not be the active session. The active session is the session that is currently using the keyboard or is waiting for keyboard input. The current session is the one in which the macro is running.

To determine if the session in which the macro is running is the active session, test the `session` function.
**sessname (function)**

Use *sessname* to find out the name of another session.

**Format**

\[ x$ = \text{sessname}(\text{integer}) \]

**Comments**

*sessname* returns the name of the session represented by \( \text{integer} \). If there is no session with that number, a null string is returned.

You can use this function to find out which sessions are running concurrently.

**Example**

```
p\int \text{sessname}(1), \text{sessno}(\text{sessname}(1))
```

In this example, the macro displays the name and number of the session identified by the integer 1.

**See Also**

*sessno*
**sessno (function)**

Use `sessno` to find out the session number of a session.

**Format**

```
x = sessno [(string)]
```

**Comments**

`sessno` returns the number of the session whose name is `string`. You do not have to include the .ADP file extension. If there is no session with that name, 0 is returned. If you do not specify an argument, `sessno` returns the number of open sessions.

As with the `sessname` function, you can use `sessno` to find out which sessions are running concurrently.

**Example**

```
if sessno ("TCPA_1") then
  print "A TCPA session exists."
```

In this example, the macro displays a message if one of the currently open sessions is TCPA_1.ADP.

**See Also**

`sessname`
**show (statement)**

Use `show` to redisplay a minimized session window.

**Format**

```
show
```

**Comments**

This command redisplay a session window that was previously minimized with the `hide` statement.

To redisplay the Accessory Manager application window, use the `restore` statement.

**Example**

```
show
```

**See Also**

`hide, restore, zoom`
showallquickpads (statement)

Use showallquickpads to show all of the QuickPads that are loaded for the current session.

Format

showallquickpads

Comments

This statement displays all of the QuickPads that were previously hidden.

Note: The QuickPads for the session must already be loaded, using the loadquickpad statement.

Example

showallquickpads

See Also

hideallquickpads, hidequickpad, loadquickpad, showquickpad
showquickpad (statement)

The showquickpad statement is supported only for backward compatibility. Refer to “loadquickpad (statement)” on page 237.
size (statement)

Use size to change the size of the Accessory Manager application window.

Format  

size x, y

Comments  

This statement changes the size of the Accessory Manager application window. The window can be made larger or smaller than its current size.

x and y are the horizontal and vertical size, in pixels.

The range of coordinates is determined by the resolution of the video adapter and monitor in use.

Example  

size 200, 350

In this example, the application window is resized to be 200 pixels wide and 350 pixels high.

See Also  

maximize, minimize, move, restore
slice (function)

Use slice to return portions of a string.

Format

\[ x$ = \text{slice}(\text{string}, \text{integer} ... \] 
\[ [, \text{delin\_str} [, \text{where\_int}]]) \]

Comments

slice returns portions of strings. \text{string} is the string that you want to work with. It is divided into substrings as delineated by \text{delin\_str}. For example, the string \text{alpha beta gamma} consists of three substrings (alpha, beta, and gamma) which are delimited by spaces. \text{delin\_str} can be a space, comma, or any other delimiter. (If \text{delin\_str} is omitted, a space is assumed.) You can specify more than one delimiter (for example, \text{";:"}).

When you use slice, the substring in integer position is returned. For example, if the string consists of three substrings and integer is 2, the second substring is returned.

where_int specifies where the function is to begin its analysis in string.

Example 1

\[ \text{sub\_string} = \text{slice}(\text{"alpha beta gamma"}, \text{2}) \]

In this example, slice returns beta.

Example 2

\[ \text{print slice}(\text{"alpha, beta, gamma"}, \text{2}, \text{","}) \]

In this example, beta is displayed on the screen.

Example 3

\[ \text{sub\_string} = \text{slice}(\text{"alpha, beta gamma.delta"}, \text{...} \] 
\[ 3,\text{","}) \]

In this example, slice returns delta.

See Also

left, mid, right, strip, subst
startup (system variable)

Use `startup` to read or set the name of a macro to run when Accessory Manager is started.

| Note: EXTRA! Enterprise for Accessory Manager sessions do not support this system variable. |

**Format**

```
startup = string
```

**Comments**

`startup` sets or reads the name of the macro to run automatically when you run Accessory Manager. If `startup` is null, no macro is run at start-up time.

`string` must be a valid file name. You do not have to include the .XWC file extension.

**Example 1**

```
startup = "AUTOEXEC"
```

In this example, a macro called AUTOEXEC.XWC runs when Accessory Manager is started.

**Example 2**

```
startup = ""
```

In this example, `startup` is null, so no macro is run when Accessory Manager is started.

**See Also**

`script`
str (function)

Use `str` to convert a number to string format.

**Format**

\[ x$ = str(number) \]

**Comments**

`str` converts numbers to strings. `number` can be a real (floating point) number or an integer. `str` does not add any leading or trailing spaces.

**Example 1**

```
print 2 : print str(2) : print length(str(2))
```

In this example, the macro displays three lines. The first line contains the integer 2. The second line contains the string that results from converting integer 2 to a string. The last line contains the length of the string displayed in line 2.

**Example 2**

```c
reply str(shares_to_buy)
```

In this example, the macro sends the string equivalent of `shares_to_buy` to the host.

**Example 3**

```c
integer counter
string items[10]
for counter = 1 to 10
    items[counter] = "item" + str(counter)
    print items[counter]
next
```

In this example, the macro declares `counter` as an integer and `items` as an array of ten strings. The `for...next` construct is used to display the individual elements in the array.

**See Also**

`intval`, `val`
strip (function)

Use strip to return a string with certain characters removed.

Format

\[ x$ = \text{strip}(\text{string}[, \text{wild}[, \text{where_int}]]) \]

Comments

strip removes unwanted characters from strings. This function is useful for removing unwanted characters from lines read from word processing text files, leading zeros, and similar characters.

\text{string} is the string to work with. \text{wild} can be either the string of characters that you want to remove from \text{string} or an integer that represents the Accessory Manager character classes that you want to remove. (For a list of these integers, refer to "class (function)" on page 141.) The default value for \text{wild} is a space.

\text{where_int} can be one of the following:

<table>
<thead>
<tr>
<th>Value</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Strip all occurrences of \text{wild}. This is the default.</td>
</tr>
<tr>
<td>1</td>
<td>Strip from the right side, stopping at the first occurrence of a character not in \text{wild}.</td>
</tr>
<tr>
<td>2</td>
<td>Strip from the left side, stopping at the first occurrence of a character not in \text{wild}.</td>
</tr>
<tr>
<td>3</td>
<td>Strip from both the right and left sides, stopping on each side at the first occurrence of a character not in \text{wild}.</td>
</tr>
</tbody>
</table>

Example 1

\text{print} \text{strip}("0123456", "0", 2)

In this example, the macro displays 123456.

Example 2

\text{print} \text{strip}("Sassafras", "as", 0)

In this example, the macro prints fr.

Example 3

\text{reply} \text{strip}(\text{strip(\text{user}\_\text{resp}, \text{junk}, 0), ",", 3})

In this example, the macro first strips out \text{junk} from \text{user}\_\text{resp} and then strips leading and trailing spaces from what remains of \text{user}\_\text{resp}. The result is sent to the host.

See Also

left, mid, right, slice, subst
stroke (function)

Use stroke to wait for the next keystroke from the keyboard.

Format

\[ x = \text{stroke} \]

Comments

stroke is similar to the inkey function, but stroke stops the macro to wait for a keystroke and returns the value of the keystroke.

The value returned is the ASCII value of the key pressed for the printable characters (0–127 decimal) and special keystrokes such as the arrow keys, function keys, and special-purpose keys. (Refer to “inkey (function)” on page 225 for a list of keys and their corresponding numbers.)

Example

print "Press a key to see its value"; : print stroke

In this example, the macro prints a message followed by the value of the key that is pressed.

See Also

inkey
Use `subst` to return a string with certain characters substituted.

**Format**

\[ x\$ = subst(string, old\_str, new\_str) \]

**Comments**

`subst` searches `string` for each occurrence of `old\_str` and substitutes the characters in `new\_str`.

**Example**

```c
print subst("alpha", "a", "b")
```

In this example, the macro prints `blphb`.

**See Also**

left, mid, right, slice, strip
systime (function)

Use systime to return the number of ticks Accessory Manager has been active.

Format

\[ x = \text{systime} \]

Comments

systime returns the number of ticks that Accessory Manager has been active. (One tick is one tenth of a second.) You can use systime in delay loops, random number routines, and similar routines.

To determine the number of ticks that a session has been online, use the ontime function.

Example 1

\[ \text{print systime} \]

In this example, the value of systime is displayed.

Example 2

\[ \text{if systime mod 100 = 0 then ...} \]

In this example, the macro takes some action if the value of systime divided by 100 is zero.

See Also

ontime
tabwidth (module variable)

Use `tabwidth` to determine the number of spaces a tab character moves the cursor.

**Format**

```
tabwidth = integer
```

**Comments**

This variable determines the number of spaces that the cursor moves when the tab character is received. `integer` can be any number from 1 to 80. The default is 8.

**Example**

```
tabwidth = 15
```

In this example, `tabwidth` is set to 15 spaces.
**terminal (system variable)**

Use `terminal` to read or set the type of the terminal emulation used by the session.

**Note**: EXTRA! Enterprise for Accessory Manager 3270 and 5250 sessions do not support this item; VT™ sessions do support it.

**Format**

```
terminal = string
```

**Comments**

`terminal` specifies the type of terminal emulation to use for the current session. `string` can be one of the following:

<table>
<thead>
<tr>
<th>String</th>
<th>Sub-Models (use the termmodel variable)</th>
<th>Emulation Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DCAT27</td>
<td>None</td>
<td>T 27</td>
</tr>
<tr>
<td>AMUTS</td>
<td>UTS20, UTS40, UTS60</td>
<td>UTS</td>
</tr>
</tbody>
</table>

**Note**: You cannot change a session from one terminal emulation type to another. For example, you cannot change a T 27 session to a UTS session. However, you can change from one sub-model to another. For example, you can change from a UTS 20 to a UTS 60 session.

For more information about terminal tools, refer to Chapter 7, "Connection, Terminal, and File Transfer Tools."

**Example 1**

```
assume terminal "AMUTS"
terminal = "AMUTS"
termmode = "UTS60"
```

This example shows how to load UTS 60 terminal emulation.

**Example 2**

```
print terminal
```

This example shows how to print the current terminal emulation selection.

**See Also**

assume, device, protocol
**terminate (statement)**

Use `terminate` to exit Accessory Manager.

**Format**

```
terminate
```

**Comments**

`terminate` exits Accessory Manager.

To close just a session, use the `quit` statement.

**Example**

```
clear
print "Accessory Manager will close in 5 seconds."
for i = 1 to 5
    print at 5, 5, time(-1)
    wait 1 second
next
terminate
```

In this example, the macro clears the window and then displays a message on the screen. Next, using the `for...next` construct, the macro displays the current time once every second until five seconds have elapsed. Finally, it closes Accessory Manager.

**See Also**

`quit`
time (function)

Use time to return a formatted time string.

Format

\[ x \$ = \text{time}(\text{integer}) \]

Comments

time returns the time in the correct format for the operating system country code.

\text{integer} is required; it is the number of seconds elapsed since midnight. You can use \text{-1} as the argument to indicate the current number of elapsed seconds since midnight.

Example 1

print time(-1)

This example prints the current time.

Example 2

\[ x = \text{time}(32431) \]

In this example, the time represented by 32,431 seconds after midnight is returned in \( x \).

Example 3

open output "time.tst" as #1
write #1, "The file open time is " + time(-1)
while online
  string_in = nextline
  write line #1, string_in
wend
close #1

In this example, the file TIME.TST is opened for output, and a phrase is written to the file using the write statement. While the macro is online, each line of text from the host is written to the file. Then the file is closed.

See Also

curhour, curminute, cursecond
timeout (system variable)

Use timeout to determine the status of the most recent nextline, wait, or watch...endwatch statement.

**Format**

`timeout`

**Comments**

timeout is true or false indicating whether the last nextline, wait, or watch...endwatch statement timed out. timeout is true if the statement exceeded the time specified before finding the condition for which it was looking.

**Example**

```
repeat
  reply
    wait 1 second for "Login:"
  until timeout = false
```

This example uses the timeout system variable and wait statement to log on to a host. In this case, the host wants a number of carriage returns so it can check the baud rate, parity, and stop bits. The carriage returns should be sent about once every second, and it will take an arbitrary number of carriage returns before the host returns the login prompt. When it is ready, the host sends the phrase Login:

**See Also**

nextline, wait, watch...endwatch
trace (statement)

Use trace to trace how the lines in a macro are executing.

**Format**

```
trace option
```

**Comments**

trace can be useful for debugging macros.

*option* is one of the following:

<table>
<thead>
<tr>
<th>Value</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>on</td>
<td>The macro displays source macro line numbers as the statements in the macro are executed.</td>
</tr>
<tr>
<td>off</td>
<td>The macro does not display source macro line numbers as the statements in the macro are executed.</td>
</tr>
</tbody>
</table>

**Example**

```
trace on
```

In this example, tracing is activated.

**See Also**

genlines
track (statement)

Use the track statement to watch for strings or keystrokes while online.

**Format**

```
track [tracknum, ] condition
```

**Comments**

track lets you check for any number of events or incoming strings while the macro is online, and then take some action based on which events occur.

track events take precedence over wait and watch events. If a track event occurs while a macro is at a wait or watch, the wait or watch is terminated and program control passes to the next statement. If you use track routine (described below), control passes to the specified subroutine.

You can check events that you are tracking only at a wait or watch. If you do not use track routine, you have to check the event with an if...then...else statement.

In the track statement, tracknum is the track number for the track statement. You should include tracknum unless the condition is routine label | procedure or clear. You can have any number of track statements active at one time. You can get an available track number with the freetrack function. Track numbers stay active as long as the macro that set them is still running. When the macro ends, the track numbers are closed.
**Chapter 6 CASL Language**

**Condition** is one or more of the following, separated by commas:

<table>
<thead>
<tr>
<th>Condition</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>[case] [space]</td>
<td><strong>string</strong> When the string specified in <strong>string</strong> is received, the value of the corresponding track function is set to true.</td>
</tr>
<tr>
<td>case indicates</td>
<td>the <strong>case</strong> of <strong>string</strong> must be matched. If <strong>case</strong> is omitted, the <strong>case</strong> of <strong>string</strong> is ignored.</td>
</tr>
<tr>
<td>space indicates</td>
<td>that all white-space characters in <strong>string</strong> (such as spaces or tabs) must be matched. If <strong>space</strong> is omitted, white space is ignored.</td>
</tr>
<tr>
<td><strong>string</strong> can</td>
<td>be any string or one of the following special sequences:</td>
</tr>
<tr>
<td><strong>Sequence</strong></td>
<td><strong>Meaning</strong></td>
</tr>
<tr>
<td>~_ (underscore)</td>
<td>Any white-space character</td>
</tr>
<tr>
<td>~A</td>
<td>Any uppercase letter</td>
</tr>
<tr>
<td>~a</td>
<td>Any lowercase letter</td>
</tr>
<tr>
<td>~#</td>
<td>Any digit (0–9)</td>
</tr>
<tr>
<td>~X</td>
<td>Any letter or digit</td>
</tr>
<tr>
<td>~?</td>
<td>Any single character</td>
</tr>
</tbody>
</table>

A tilde (~) with a dash (-) followed by a special sequence character indicates that one or more occurrences of the sequence should be tracked. For example, ~# indicates that one or more occurrences of any digit (0–9) should be tracked.

For this condition to work properly, the session must be online.

| quiet time      | **quiet** indicates that the macro should wait until the communication line is quiet (no characters are received) for the amount of time specified in **time**. |
| time is one of  | the following time expressions:                                                                                                         |
| n hours         |                                                                                                                                      |
| n minutes       |                                                                                                                                      |
| n seconds       |                                                                                                                                      |
| n ticks (1/10 second each) |                                                                                                                                      |

For this condition to work properly, the session must be online.
Chapter 6 CASL Language

To stop tracking a particular item, set the item to a null string.

You can use the match system variable to return the string found during the last track operation.

<table>
<thead>
<tr>
<th>Condition</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>key stroke_value</td>
<td>key specifies a keyboard character to track.</td>
</tr>
<tr>
<td>stroke_value</td>
<td>stroke_value is the ASCII value (0–127) of the key pressed. For the values for special keystrokes (such as the function keys or arrow keys), refer to &quot;inkey (function)&quot; on page 225. The keyboard character comes from the local keyboard, not the communication line.</td>
</tr>
<tr>
<td>routine procedure</td>
<td>Use track routine to designate a subroutine or procedure that handles the track event. procedure is the name of the subroutine or procedure.</td>
</tr>
<tr>
<td>clear</td>
<td>Use track clear to clear all tracked items and reset all of the track flags.</td>
</tr>
</tbody>
</table>

To stop tracking a particular item, set the item to a null string.

Example

track clear
track 1, space "system going down"
track 2, case space "no more messages"
track 3, case "thank you for calling"
track 4, key 833 -- Alt+A
track 5, quiet 1 minute
track routine check_track

wait for key 27 -- Esc
...
...
end

label check_track
if track(1) then
    { bye : wait 8 minutes : new "megamail" : end }
if track(2) then goto send_outbound_messages
if track(3) then { bye : end }
if track(4) then end
if track(5) then { alarm 6 : reply : return }

This example uses both the track statement and the track function to watch for problems or Alt+A during an e-mail session.

See Also
freetrack, inkey, match, track (function), wait, watch...endwatch
track (function)

Use the track function to determine if a string or event for which a track statement is watching has occurred.

Format

\[
\begin{align*}
x &= \text{track} \\
\text{or} \\
x &= \text{track(tracknum)}
\end{align*}
\]

Comments

The track function checks if one of the strings or events for which a track statement is watching has been received and, if so, which one. Use this function with the wait and watch...endwatch statements.

track events take precedence over wait and watch events. If a track event occurs while a macro is at a wait or watch, the wait or watch is terminated and program control passes to the next statement. If you use track routine, control first passes to the specified subroutine.

You can check events that you are tracking only at a wait or watch. If you do not use track routine, you have to check the event with an if...then...else statement.

tracknum is the track number for the track event. The track function is set to true when the string or event in the corresponding track statement is received.

The first form of the track function \((x = \text{track})\) returns the value of the lowest track number that has had an event occur. If none of the track statements has found a match, the track function returns false.

The second form of the track function \((x = \text{track(tracknum)})\) returns true if the specified track event has occurred. Checking the function clears it.
Chapter 6 CASL Language

Example

track 1, "System is going down"
wait for key 27
if track(1) then reply "logout"

In this example, the track statement is using track number 1 to watch for a string. The macro is waiting for the Esc key. The track function for track 1 is checked to determine if the string was found, and if so, a logout message is sent to the host.

See Also

match, track (statement), wait, watch...endwatch
trap (compiler directive)

Use `trap` to control error trapping.

**Format**

```plaintext
trap option
```

**Comments**

`trap` lets you control whether the macro continues to run when errors occur that would normally stop the macro.

`option` is one of the following:

<table>
<thead>
<tr>
<th>Value</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>on</td>
<td>An error condition does not interrupt the running of the macro.</td>
</tr>
<tr>
<td>off</td>
<td>An error condition interrupts the running of the macro. This is the default state.</td>
</tr>
</tbody>
</table>

When `trap` is on, use the `error` function and the `errclass` and `errno` system variables to determine the occurrence, class, and number of the error. When the `error` function is tested for a value, it is cleared out. If it is not cleared, the next error that occurs will stop the macro.

In general, it is best to set `trap` to on just prior to a statement that might generate an error, and then set it to off immediately after the statement executes. Be sure to check the error return codes because a subsequent statement may reset the codes.

**Example**

```plaintext
string fname
fname = "*.exe"
trap on
send fname
trap off
if error then goto error_handler
```

In this example, the macro branches to an error-handling routine if an error occurs when the `send` statement is executed.

**See Also**

`errclass`, `errno`, `error`
true (constant)

Use `true` to set a variable to logical true.

**Format**

```
x = true
```

**Comments**

`true` is always logical true. Like its complement `false`, `true` exists as a way to set variables on and off. If `true` is converted to an integer, its value is 1.

**Example**

```
x = 1
done = false
while not done
   x = x + 1
   if x = 10 then done = true
wend
```

In this example, the statements in the `while...wend` construct are repeated until `done` is true.

**See Also**

`false`, `off`, `on`
unloadallquickpads (statement)

Use unloadallquickpads to unload all QuickPads for the current session.

Format
unloadallquickpads

Comments
This statement unloads all loaded QuickPads for the current session. To unload one specific QuickPad, use the unloadquickpad statement.

Example
unloadallquickpads

See Also
hideallquickpads, hidequickpad, loadquickpad, showallquickpads, showquickpad, unloadquickpad
unloadquickpad (statement)

Use unloadquickpad to unload the specified QuickPad for the current session.

**Format**

```
unloadquickpad string
```

**Comments**

This statement unloads the QuickPad specified in `string`. You do not have to specify the .EQP file extension.

**Example**

```
unloadquickpad "apad"
```

In this example, the QuickPad APAD.EQP is unloaded.

**See Also**

hideallquickpads, hidequickpad, loadquickpad, showallquickpads, showquickpad, unloadallquickpads
upcase (function)

Use upcase to convert a string to uppercase letters.

Format

\[ x\$ = \text{upcase}(\text{string}) \]

Comments

upcase converts only the letters a–z to uppercase characters. Numerals, punctuation marks, and notational symbols are unaffected.

Example

```casl
string yn
print "Do this again?";
input yn
if upcase(yn) = "Y" then goto start
```

In this example, the character typed by the user (which is stored in the \texttt{yn} variable) is checked to determine if it is an uppercase \texttt{Y}. If it is, the macro branches to the label \texttt{start}.

See Also

lowcase
userid (system variable)

Use userid to read or set a user number or identifier for a session.

Format

userid = string

Comments

userid sets or reads the user identification associated with the current session. userid is limited to 40 characters.

Note: To set this parameter using Accessory Manager, click Session Preferences from the Options menu, click the CASL Macro tab, and type the desired string in the User ID text box.

Example 1

userid = "76004,302"

In this example, userid is set to the specified string.

Example 2

reply userid

In this example, userid is sent to the host.

Example 3

userid = ""

In this example, userid is cleared.
val (function)

Use val to return the numeric value of a string.

Format

\[
x = \text{val}(\text{string})
\]

Comments

Like the intval function, val returns a numeric value. However, val returns a real (floating point) number rather than an integer. The val function evaluates string for its numerical meaning and returns that meaning as a real number. Leading white-space characters are ignored, and string is evaluated until a non-numeric character is encountered.

The characters that have meaning to the val function are 0–9, ., e, E, -, and +.

Example

\[
\text{num} = \text{val}(\text{user_input_string})
\]

In this example, user_input_string is converted to a real number and returned in num.

See Also

intval, str
version (function)

Use `version` to return the Accessory Manager version number.

**Format**

\[ x$ = \text{version} \]

**Comments**

`version` returns the Accessory Manager version number as a string.

To check the version number of Windows, use the `winversion` function.

**Example**

`print version`

In this example, the Accessory Manager version number is displayed.

**See Also**

`winversion`
wait (statement)

Use wait to wait for a specific event to occur or to pause the macro.

Note: EXTRA! Enterprise for Accessory Manager sessions do not support this statement.

Format

wait [time] [for condition]

Comments

The wait statement waits the amount of time specified in time for the specified condition to occur.

time is one of the following time expressions:

- n hours
- n minutes
- n seconds
- n ticks (1/10 second each)

If time is included and the specified condition occurs within that time period, the macro resumes running.

If time is included and the specified condition does not occur within that time period, the timeout system variable returns true.

If time is omitted, the macro waits indefinitely for the specified condition to occur.

The wait time construct can be used whether the session is offline or online.
condition is one or more of the following, separated by commas:

<table>
<thead>
<tr>
<th>Condition</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>[case] [space] string</td>
<td>When the string specified in string is received, the macro continues.</td>
</tr>
</tbody>
</table>

- **case** indicates that the case of string must be matched. If case is omitted, the case of string is ignored.
- **space** indicates that all white-space characters in string (such as spaces or tabs) must be matched. If string ends with a space and you want to match that space, you must use <Space> in your string. If space is omitted, white space is ignored.

- **string** can be any string or one of the following special sequences:
<table>
<thead>
<tr>
<th>Sequence</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>~_ (underscore)</td>
<td>Any white-space character</td>
</tr>
<tr>
<td>~A</td>
<td>Any uppercase letter</td>
</tr>
<tr>
<td>~a</td>
<td>Any lowercase letter</td>
</tr>
<tr>
<td>~#</td>
<td>Any digit (0–9)</td>
</tr>
<tr>
<td>~X</td>
<td>Any letter or digit</td>
</tr>
<tr>
<td>~?</td>
<td>Any single character</td>
</tr>
</tbody>
</table>

For this condition to work properly, the session must be online.

<table>
<thead>
<tr>
<th>quiet time</th>
<th>quiet indicates that the macro should wait until the communication line is quiet (no characters are received) for the amount of time specified in time.</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>time is one of the following time expressions:</td>
</tr>
<tr>
<td></td>
<td>- n hours</td>
</tr>
<tr>
<td></td>
<td>- n minutes</td>
</tr>
<tr>
<td></td>
<td>- n seconds</td>
</tr>
<tr>
<td></td>
<td>- n ticks (1/10 second each)</td>
</tr>
</tbody>
</table>

For this condition to work properly, the session must be online.
When writing very long macros, you might need to add some `wait` statements to give Accessory Manager time to process the macro. To do this, add `wait 5 ticks` at several points throughout the macro.

If you have problems with the `wait for string` construct (for example, if data seems to be missing from the display), add a second `wait` statement. You can wait for a string that is not at the end of a data stream and still display the entire data stream by using two `wait` statements in sequence as follows:

```plaintext
wait for "string"
/* data up to and including string is displayed */
wait for quiet 1 tick
/* the rest of the data stream is displayed */
```

**Example 1**

```
wait for "Login:" : reply userid
```

In this example, the macro waits indefinitely for the specified phrase and sends the information stored in the `userid` system variable to the host.

**Example 2**

```
wait 1 second for "Hello"
```

In this example, the macro waits one second for the specified phrase.
Example 3

```plaintext
wait for "A", "B", "C"
string_in = match
  case string_in of
    "A" : reply 'We received an "A"'
    "B" : reply 'We received a "B"'
    "C" : reply 'We received a "C"'
endcase
```

In this example, the macro waits for any one of the characters A, B, or C. Depending on which value is received, the appropriate response is sent to the host.

Example 4

```plaintext
wait 20 seconds for "in:" : if timeout then
goto no_ans
```

In this example, the macro waits 20 seconds for a phrase. If the phrase does not arrive within 20 seconds, the macro branches to the label `no_ans`.

Example 5

```plaintext
wait for count 10
```

In this example, the macro waits until ten characters are received.

Example 6

```plaintext
wait for case "UserID:"
```

In this example, the macro waits for an exact uppercase and lowercase match for the `UserID:` prompt.

See Also

inkey, match, online, timeout, track (statement), watch...endwatch
watch...endwatch (statements)

Use `watch...endwatch` to watch for one of several strings of text from the communication device or for a keystroke.

**Note:** EXTRA! Enterprise for Accessory Manager sessions do not support these statements.

### Format

```
watch [time] for
    [[case] [space] string : [statement group]]
    [quiet time] : [statement group]
    [key stroke value] : [statement group]
    [count integer] : [statement group]
endwatch
```

### Comments

The `watch` statement waits the length of time specified in `time` for one of the specified conditions to occur and then performs the specified `statement group`.

- `time` is one of the following time expressions:
  - \( n \) hours
  - \( n \) minutes
  - \( n \) seconds
  - \( n \) ticks (1/10 second each)

If `time` is included and the specified condition occurs within that time period, the specified statement group is performed, and the program logic then continues with the statement following `endwatch`.

If `time` is included and the specified condition does not occur within that time period, the `timeout` system variable returns `true`.

If `time` is omitted, the macro waits indefinitely for the specified condition to occur.
The following table explains the `watch` conditions:

<table>
<thead>
<tr>
<th>Condition</th>
<th>Result</th>
</tr>
</thead>
</table>
| `[case] [space] string` | When the string specified in `string` is received, the subsequent `statement group` is performed.  
  *case* indicates that the case of `string` must be matched. If `case` is omitted, the case of `string` is ignored.  
  *space* indicates that all white-space characters in `string` (such as spaces or tabs) must be matched. If `space` is omitted, white space is ignored.  
  *string* can be any string or one of the following special sequences: |
| Sequence | Meaning |
| ~_ (underscore) | Any white-space character |
| ~A | Any uppercase letter |
| ~a | Any lowercase letter |
| ~# | Any digit (0–9) |
| ~X | Any letter or digit |
| ~? | Any single character |

For this condition to work properly, the session must be online.

`quiet time` | `quiet` indicates that the macro should wait until the communication line is quiet (no characters are received) for the amount of time specified in `time` before performing the `statement group`. |
| `time` is one of the following time expressions: |

- n hours |
- n minutes |
- n seconds |
- n ticks (1/10 second each) |

For this condition to work properly, the session must be online.
Chapter 6 CASL Language

**watch...endwatch** (statements)

**statement group** is any CASL statement.

The **watch**...**endwatch** construct is not a looping construct. When one of the **watch** conditions is met, the macro executes the appropriate statement(s). To use these statements in a loop, place them inside a **while**...**wend** construct.

**Example 1**

```
watch for
   "Login:" : goto login_procedure
   "system down" : goto cant_log_in
   quiet 10 minutes : goto system_is_dead
   key 27 : reply "logoff" : bye
end
endwatch
```

In this example, the macro watches for one of the specified events. If any of the events occurs, the statements to the right of the colon are executed, and the **watch**...**endwatch** construct is completed.

**Example 2**

```
while online
   watch for
      "graphics" : reply "Yes"
      "first name" : reply userid
      "password" : reply password : end
   endwatch
wend
```

This example includes the **watch**...**endwatch** construct in a **while**...**wend** loop. The **while**...**wend** construct continues to loop until **watch** receives the **password** prompt.

**See Also**

**inkey**, **match**, **track**, **wait**, **while**...**wend**
weekday (function)

Use `weekday` to return the number of the day of the week.

**Format**

```plaintext
x = weekday[(integer)]
```

**Comments**

`weekday` returns the number of the current day of the week. Sunday is 0, Monday is 1, and so on.

If `integer` is specified, `weekday` returns the day of the week for a given date in the past or future.

**Example**

```plaintext
print weekday, weekday(365)
```

For a Friday, the macro in this example prints 5, a tab, and 1.

**See Also**

`curday`
while...wend (statements)

Use while...wend to perform a statement or group of statements as long as a specified condition is true.

Format
while expression
  ...
  ...
  ...
wend

Comments
while...wend lets you perform one or more statements as long as a certain expression is true.

expression is any logical expression. It can be a combination of numerical, Boolean, or string comparisons that can be evaluated as either true or false.

Unlike the repeat...until construct, the while...wend construct is not executed at all if the expression is false the first time it is evaluated.

wend indicates the end of the conditional statements.

When using any looping construct, make sure that the terminating condition (expression) will eventually become true, or that there is some other exit from the loop.

Example
x = 1
while x <> 100
  print x
  x = x + 1
wend

In this example, the macro prints the numbers 1 through 99.

See Also
repeat...until
winchar (function)

Use winchar to return the ASCII value of a character read from a session window.

Format

\[ x = \text{winchar}(\text{row}, \text{col}) \]

Comments

winchar reads a character from a session window at row, col. The winchar function helps you determine the results of operations not under macro control, such as the appearance of a certain character at a certain location on the screen while under the control of a host.

Example

\[ \text{char1} = \text{winchar}(1, 1) \]

In this example, the character at row 1, column 1 is stored in char1.

See Also

nextchar, nextline, winstring
**winsizex (function)**

Use `winsizex` to return the number of visible columns in the session window.

**Format**

```
x = winsizex
```

**Comments**

`winsizex` returns the number of visible columns in the session window. This function is useful in macros that display information on the screen and have to accommodate the size of the session window.

**Example 1**

```
print winsizex
```

In this example, the macro prints the number of visible columns in the session window at its current size.

**Example 2**

```
if winsizex < 80 then zoom
```

If the session window is less than 80 columns in width, this statement maximizes it.

**See Also**

`winsizey`
winsizey (function)

Use **winsizey** to return the number of visible rows in the session window.

**Format**

\[ x = \text{winsizey} \]

**Comments**

**winsizey** returns the number of visible rows in the session window. This function is useful in macros that display information on the screen and have to accommodate the size of the session window.

**Example**

\[ \text{if winsizey} < 24 \text{ then zoom} \]

If the session window is less than 24 rows in length, this statement maximizes it.

**See Also**

**winsizex**
winst re (function)

Use winstring to return a string read from a session window.

Format

\[ x\$ = \text{winst re}(\text{row}, \text{col}, \text{len}) \]

Comments

winst re reads a string of characters from the session window, beginning at row, col, for len characters, with any trailing spaces removed.

winst re lets you determine the results of operations not under macro control, such as the appearance of a certain string at a certain location on the screen while under the control of a host.

Example

\[
\text{string data} \\
\text{data} = \text{winst re}(10, 10, 11) \\
\text{if data} = \"Login name:\" \text{then reply userid} \\
\]

In this example, if the phrase Login name: appears in the session window beginning at row 10, column 10, then the userid system variable is sent to the host.
winversion (function)

Use \texttt{winversion} to check the Windows version number.

\textbf{Format} \quad \texttt{x$ = \text{winversion}}

\textbf{Comments} \quad \texttt{winversion} returns the Windows version number as a string.

To check the version number of Accessory Manager, use the \texttt{version} function.

\textbf{Example} \quad \texttt{print \ \text{winversion}}

In this example, the macro displays the Windows version number on the screen.

\textbf{See Also} \quad \texttt{version}
**Chapter 6 CASL Language**

### write (statement)

Use `write` to write lines containing comma-delimited fields of ASCII data to a sequential file.

**Format**

```
write [#filename, ] [item] [{, | ;} ... [item]] ... [;]
```

**Comments**

The `write` statement writes lines containing comma-delimited fields of ASCII data to a sequential file. This statement operates only on files opened in output or append modes.

*filename* must be an open file output number. If *filename* is omitted, the file number stored in the variable *defoutput* is assumed.

Each `write` adds the specified items to the file, with each separated from the next by a comma. To suppress the commas in the output file, separate the items in the list with semicolons instead of commas. If an *item* includes a comma or quotation marks, use the `quote` function to enclose the item in quotation marks.

Normally, `write` terminates each addition to the file with a carriage-return/line-feed (CR/LF). To suppress the CR/LF, use the trailing semicolon.

**Example 1**

```
open output file_name as #1
write #1, alpha, beta, gamma;
close #1
```

In this example, the macro opens a file, writes the specified strings to the file, and closes the file.

**Example 2**

```
write #1, quote(var1), quote(var2), quote(var3)
```

In this example, the macro encloses the data strings in quotation marks before writing them to the file.

**See Also**

`defoutput`, `open`, `quote`, `write line`
write line (statement)

Use \texttt{write line} to write lines of data to a sequential file.

**Format**

\begin{verbatim}
write line [\#filenum, ] [item] [\{, | ;} ... [item]] ... [;]
\end{verbatim}

**Comments**

The \texttt{write line} statement writes a line of data to a sequential file. This statement operates only on files opened in output or append modes.

\texttt{filenum} must be an open file output number. If \texttt{filenum} is omitted, the file number stored in the variable \texttt{defoutput} is assumed.

To write each item on a separate line, separate the items with a comma. To write the data on a single line rather than separate lines, separating the items with a semicolon.

Normally, \texttt{write line} terminates each addition to the file with a carriage-return/line-feed (CR/LF) pair. To suppress the CR/LF, use the trailing semicolon.

**Example 1**

\begin{verbatim}
write line "end of test"
\end{verbatim}

In this example, the text \texttt{end of test} is written to a file. Since the file number is not specified, the default file number in \texttt{defoutput} is used.

**Example 2**

\begin{verbatim}
write line #1, some_text
\end{verbatim}

In this example, the macro writes the contents of \texttt{some_text} to the file identified by the file number 1.

**See Also**

\texttt{defoutput}, \texttt{open}, \texttt{write}
xpos (function)

Use xpos to find out the column location of the cursor.

Format

\[ x = \text{xpos} \]

Comments

xpos returns the number of the column in which the cursor is located.

Example 1

\[ \text{cur}_\text{col} = \text{xpos} \]

In this example, the macro assigns the cursor’s current column position to the \text{cur_col} variable.

Example 2

\[ \text{if } \text{xpos} = \text{winsizex} - 1 \text{ then alarm} \]

In this example, the PC sounds an alarm if the cursor is located one column less than the size of the window.

See Also

ypos
ypos (function)

Use ypos to find out the row location of the cursor.

Format

\[ x = ypos \]

Comments

ypos returns the number of the row in which the cursor is located.

Example 1

\[ cur\_row = ypos \]

In this example, the macro assigns the cursor's current row position to the cur_row variable.

Example 2

\[ \text{if ypos = winsizey - 1 then alarm} \]

In this example, the PC sounds an alarm if the cursor position is one row less than the size of the window.

See Also

xpos
zoom (statement)

Use `zoom` to maximize a session window.

**Format**

```
zoom
```

**Comments**

`zoom` maximizes a session window.

To maximize the Accessory Manager application window, use the `maximize` function.

**Example**

```
if online then
  zoom
```

In this example, the session window is maximized if the session is online to the host.

**See Also**

hide, show, maximize
In This Chapter

This chapter provides information on Accessory Manager’s tools for connecting to a host, emulating a terminal, and transferring files. The chapter also lists the variables used by each tool.

Tool Concept .................................................. 364
Connection Tools .......................................... 365
Terminal Tools ............................................ 366
File Transfer Tools ........................................ 367
Using Tool Variables .................................... 368
Connection Tool Variables ............................ 369
T 27 Variables ............................................. 370
UTS Variables ............................................ 374
A tool is a code file that controls a specific aspect of a session. There are three types of tools:

- Connection tool
- Terminal tool
- File transfer tool

The tools correspond to the options on the Session Type dialog box in Accessory Manager. The connection tool corresponds to the Connection Type; the terminal tool corresponds to the Display/Device Type; and the file transfer tool corresponds to the File Transfer Protocol.

For example, a T 27 session uses the INFOConnect connection tool, the T 27 terminal tool, and the CANDE file transfer tool.

Minimally, each session must have a connection tool and a terminal tool; a file transfer tool is needed only when you want to transfer files. Each of these tools is described in detail later in this chapter.

You can configure the settings for the tools using the Settings dialog box in Accessory Manager. For example, to configure the connection tool, click Settings from the Options menu, click Connection from the Categories list box, and complete the right half of the dialog box. To configure the terminal tool, click Display from the Categories list box. To configure the file transfer tool, click File Transfer.

You can also configure many of these settings using a CASL macro. For more information, refer to “Using Tool Variables” on page 368.
Connection Tools

The connection tool determines which mechanism the session uses to communicate with the host. For example, T 27 and UTS use the INFOConnect connection tool. This connection tool lets you select the INFOConnect path to use with your session, as well as configure other options (such as the action to take if the session is disconnected, or the host graphics protocol to use).

You can configure the INFOConnect connection tool using either the Settings dialog box in Accessory Manager or a CASL macro. For information on doing this using a CASL macro, refer to “Using Tool Variables” on page 368 and “Connection Tool Variables” on page 369.

EXTRA! Enterprise for Accessory Manager and WinFTP sessions do not use the INFOConnect connection tool; they have separate connection tools of their own.

Currently, you cannot use a CASL macro to specify which connection tool to use for EXTRA! Enterprise for Accessory Manager or WinFTP sessions. To specify the connection tool, you must click Session Type from Accessory Manager’s Options menu and click the desired item from the Connection Type list box.

In addition, you cannot use a CASL macro to configure an EXTRA! Enterprise for Accessory Manager or WinFTP connection tool. To configure the connection tool, you must click Settings from the Options menu, click Connection from the Categories list box, and complete the Settings dialog box.
Terminal Tools

The terminal tool determines which kind of terminal the PC will emulate during a session. For example, the T 27 terminal tool emulates a T 27 terminal; the UTS terminal tool emulates a UTS 20, UTS 40, or UTS 60 terminal. Each terminal tool lets you interact with a particular type of host in the manner that the host expects.

You cannot change a session from one terminal emulation type to another. For example, you cannot change a T 27 session to a UTS session. However, you can change from one sub-model to another. For example, you can change from a UTS 20 to a UTS 60 session. For more information, refer to “terminal (system variable)” on page 326.

Although you cannot change the terminal tool for a session, you can configure it using either the Settings dialog box in Accessory Manager or a CASL macro. For information on doing this using a CASL macro, refer to “Using Tool Variables” on page 368, “T 27 Variables” on page 370, and “UTS Variables” on page 374.

Currently, you cannot use a CASL macro to configure the ALC or EXTRA! Enterprise for Accessory Manager terminal tools. To configure these terminal tools, you must click Settings from the Options menu, click Display from the Categories list box, and complete the Settings dialog box.
File Transfer Tools

The file transfer tools determine which file transfer protocol to use for a session. Each file transfer protocol has a unique set of rules and conventions that define, among other things, the number of bytes to send for each block of data and how to detect and correct errors.

Each product comes with its own file transfer tools. For example, T27 comes with a CANDE file transfer tool; UTS comes with a MAPPER and OS2200 file transfer tool; 3270 comes with a IND$FILE file transfer tool.

You cannot change to a file transfer protocol that is not supported by the session's terminal type. For example, you cannot change from CANDE to OS2200, since the former is designed for use with T27, and the latter for use with UTS. For more information, refer to "protocol (system variable)" on page 288.

Currently, you cannot use a CASL macro to specify which file transfer tool to use for EXTRA! Enterprise for Accessory Manager sessions. To specify the file transfer tool, you must click Session Type from Accessory Manager's Options menu and click the desired item from the File Transfer Protocol list box.

You can configure UTS's MAPPER file transfer protocol using either the Settings dialog box in Accessory Manager or a CASL macro. For information on doing this using a CASL macro, refer to "Using Tool Variables" on page 368 and "UTS Variables" on page 374.

However, you cannot use a CASL macro to configure T27's file transfer protocol (CANDE) or UTS's OS2200 file transfer protocol. To do this, you must click Settings from the Options menu, click File Transfer from the Categories list box, and complete the Settings dialog box.
Using Tool Variables

The connection, terminal, and file transfer tools have predefined variables that you can read or change using a CASL macro. These variables correspond to options that you can change on the Settings dialog box. The values for these variables are stored in each session’s .ADP file.

The variable names are stored in text files with file extensions of .PRE.

**Note:** Do not alter the .PRE files in any manner. Otherwise, compiling a macro becomes unpredictable.

To read or set a variable, use the `assume` statement to specify the tool type and file name. Then use the format `variable_name = value` to set the desired configuration option. For more information about the `assume` statement, refer to “`assume (statement)`” on page 134.

**Example**

```plaintext
assume terminal "dcat27"
CurShape = "block"
```

T 27 has a string variable CurShape that can have the values Block, Underline, or VerticalBar. This macro changes the cursor shape to a block.
## Chapter 7  Connection, Terminal, and File Transfer Tools

### Connection Tool Variables

The INFO Connect connection tool supports the variables in ICSTOOL.PRE:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>DevModel</td>
<td>String</td>
<td>An internal setting that does not appear on the Settings dialog box but determines which paths appear in the Path ID list box. The DevModel must match the OpenID.</td>
<td>All paths, Telnet/TTY paths, Unassociated paths, Unisys® A/V Series Paths, Unisys 1100/2200 paths</td>
</tr>
<tr>
<td>DynamicPath</td>
<td>Boolean</td>
<td>If this variable is true, the user must select a path from the Select INFOConnect Path dialog box. If it is false, the path specified by PathID is used automatically.</td>
<td>true, false</td>
</tr>
<tr>
<td>HostGraphics</td>
<td>Integer</td>
<td>The host graphics protocol to use with the session</td>
<td>0 = GraphX is not installed, 1 = GraphX for an 1100/2200 Series host, 2 = GraphX for an A Series host, 3 = GraphX for a UNIX® host</td>
</tr>
<tr>
<td>OpenID</td>
<td>String</td>
<td>An internal setting that does not appear on the Settings dialog box but determines which paths appear in the Path ID list box. To use this, UseOpenID must be set to true, and OpenID must match the DevModel.</td>
<td>ANSI (Telnet/TTY paths), MT (Unisys A Series paths), UTS66 (Unisys 1100/2200 paths), <strong>(unassociated paths)</strong></td>
</tr>
<tr>
<td>PathID</td>
<td>String</td>
<td>The INFOConnect path to use for the session</td>
<td>Any valid INFOConnect path name</td>
</tr>
<tr>
<td>UseOpenID</td>
<td>Boolean</td>
<td>Determines whether the connection tool lists only the INFOConnect paths matching those specified by the OpenID.</td>
<td>true, false</td>
</tr>
</tbody>
</table>
Chapter 7  Connection, Terminal, and File Transfer Tools

T 27 Variables

T 27 supports the variables in DCAT27.PRE:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>AlarmLevel</td>
<td>Boolean</td>
<td>Determines whether the PC sounds a beep when the cursor reaches a specified location</td>
<td>true, false</td>
</tr>
<tr>
<td>AlternateRS</td>
<td>Integer</td>
<td>Character to use for the record separator field delimiter</td>
<td>1–255</td>
</tr>
<tr>
<td>AlternateUS</td>
<td>Integer</td>
<td>Character to use for the unit separator field delimiter</td>
<td>1–255</td>
</tr>
<tr>
<td>AutoSizeFont</td>
<td>Boolean</td>
<td>Determines whether the font size changes with the session window size</td>
<td>true, false</td>
</tr>
<tr>
<td>ClrInForms</td>
<td>String</td>
<td>The data to clear when you clear data in forms mode</td>
<td>Unprotected, All</td>
</tr>
<tr>
<td>ColumnAlarm</td>
<td>Integer</td>
<td>Column number at which the alarm will sound (if enabled)</td>
<td>1–100</td>
</tr>
<tr>
<td>Columns</td>
<td>Integer</td>
<td>Number of columns per page</td>
<td>1–132</td>
</tr>
<tr>
<td>CR_Interp</td>
<td>String</td>
<td>The interpretation of a received CR character</td>
<td>CR, CRLF</td>
</tr>
<tr>
<td>CurShape</td>
<td>String</td>
<td>Cursor shape</td>
<td>Block, Underline, or VerticalBar</td>
</tr>
<tr>
<td>CursorWrap</td>
<td>Boolean</td>
<td>Determines whether a word wraps to the next line</td>
<td>true, false</td>
</tr>
<tr>
<td>DC1_Function</td>
<td>String</td>
<td>The interpretation of a received DC1 character</td>
<td>LineClr, StayInRcv</td>
</tr>
<tr>
<td>DC2_Function</td>
<td>String</td>
<td>The interpretation of a received DC2 character</td>
<td>ToggleForms, AdvanceDCP</td>
</tr>
<tr>
<td>DelimiterVisible</td>
<td>Boolean</td>
<td>Determines whether field delimiters are displayed or replaced by blanks</td>
<td>true, false</td>
</tr>
<tr>
<td>DispCRSym</td>
<td>Boolean</td>
<td>Determines whether a CR entered from the keyboard is displayed</td>
<td>true, false</td>
</tr>
<tr>
<td>DisplayETX</td>
<td>Boolean</td>
<td>Determines whether an ETX received from the host is displayed</td>
<td>true, false</td>
</tr>
<tr>
<td>Variable</td>
<td>Type</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------</td>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td>DisplayRcvdCR</td>
<td>Boolean</td>
<td>Determines whether a CR received from the host is displayed</td>
<td>true, false</td>
</tr>
<tr>
<td>DisplayRcvdHT</td>
<td>Boolean</td>
<td>Determines whether an HT received from the host is displayed</td>
<td>true, false</td>
</tr>
<tr>
<td>DispTabSym</td>
<td>Boolean</td>
<td>Determines whether an HT entered from the keyboard is displayed</td>
<td>true, false</td>
</tr>
<tr>
<td>ETX_Advance</td>
<td>Boolean</td>
<td>Determines whether the cursor advances one position when an ETX is received</td>
<td>true, false</td>
</tr>
<tr>
<td>FF_ClrsTabs</td>
<td>Boolean</td>
<td>Determines whether variable tabs are cleared when a form feed is received</td>
<td>true, false</td>
</tr>
<tr>
<td>Font</td>
<td>String</td>
<td>The name of the font to use</td>
<td>InterComW N, InterComW B, or a fixed-width typeface name, such as Terminal or Courier</td>
</tr>
<tr>
<td>FontSize</td>
<td>Integer</td>
<td>Point size of the font to use</td>
<td>Varies with the font</td>
</tr>
<tr>
<td>FormXmitToCursor</td>
<td>Boolean</td>
<td>Determines whether only the data up to the cursor be sent to the host</td>
<td>true, false</td>
</tr>
<tr>
<td>HostScreenInvert</td>
<td>Boolean</td>
<td>Determines whether the Host To Screen translation table will be inverted</td>
<td>true, false</td>
</tr>
<tr>
<td>HostScreenTable</td>
<td>String</td>
<td>File name of the Host To Screen translation table</td>
<td>filename</td>
</tr>
<tr>
<td>InsSpace</td>
<td>Boolean</td>
<td>Determines whether toggling on insert mode inserts a space at the cursor</td>
<td>true, false</td>
</tr>
<tr>
<td>KbdCROnly</td>
<td>Boolean</td>
<td>Determines whether the cursor stays on the current row when a CR is entered</td>
<td>true, false</td>
</tr>
<tr>
<td>LF_Interp</td>
<td>String</td>
<td>The interpretation of a received line feed character</td>
<td>LF, CRLF</td>
</tr>
<tr>
<td>LineAtATimeXmit</td>
<td>Boolean</td>
<td>Determines whether the transmit key sends only the line containing the cursor</td>
<td>true, false</td>
</tr>
</tbody>
</table>
### Chapter 7  
**Connection, Terminal, and File Transfer Tools**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>LowerCase</td>
<td>Boolean</td>
<td>Determines whether lower case characters can be entered from the keyboard</td>
<td>true, false</td>
</tr>
<tr>
<td>NoSkipField</td>
<td>Boolean</td>
<td>Determines whether the cursor stays in the current field when the field is full or goes to the next field</td>
<td>true, false</td>
</tr>
<tr>
<td>Pages</td>
<td>Integer</td>
<td>Number of terminal pages</td>
<td>1–99</td>
</tr>
<tr>
<td>RawEightBit</td>
<td>Boolean</td>
<td>Determines whether extended characters are sent to the host</td>
<td>true, false</td>
</tr>
<tr>
<td>RcvModeHold</td>
<td>Boolean</td>
<td>Determines whether the PC remains in receive mode after receiving a buffer</td>
<td>true, false</td>
</tr>
<tr>
<td>RowAlarm</td>
<td>Integer</td>
<td>Row number at which alarm sounds (if enabled)</td>
<td>1–50</td>
</tr>
<tr>
<td>Rows</td>
<td>Integer</td>
<td>Number of rows per page</td>
<td>1–50</td>
</tr>
<tr>
<td>ScreenHostInvert</td>
<td>Boolean</td>
<td>Determines whether the Screen to Host translation table will be inverted</td>
<td>true, false</td>
</tr>
<tr>
<td>ScreenHostTable</td>
<td>String</td>
<td>File name of the Screen to Host translation table</td>
<td>filename</td>
</tr>
<tr>
<td>ExtendedSOSI</td>
<td>Boolean</td>
<td>Determines whether to use SO and SI to send extended characters</td>
<td>true, false</td>
</tr>
<tr>
<td>TranslateSOSI</td>
<td>Boolean</td>
<td>Determines whether SO and SI will be used to receive extended characters</td>
<td>true, false</td>
</tr>
<tr>
<td>SOH_ClrScreen</td>
<td>Boolean</td>
<td>Determines whether the start of each buffer clears the screen</td>
<td>true, false</td>
</tr>
<tr>
<td>SOH_ExitsForms</td>
<td>Boolean</td>
<td>Determines whether the start of each buffer exits forms mode</td>
<td>true, false</td>
</tr>
<tr>
<td>SpcfyKeyHex</td>
<td>Boolean</td>
<td>Determines whether the Specify key sends the cursor position in hexadecimal</td>
<td>true, false</td>
</tr>
<tr>
<td>SpcfySendsPage</td>
<td>Boolean</td>
<td>Determines whether the Specify key sends the page number as well as the cursor position</td>
<td>true, false</td>
</tr>
</tbody>
</table>
### T 27 Variables

**Chapter 7  Connection, Terminal, and File Transfer Tools**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>SpecialScroll</td>
<td>Boolean</td>
<td>Determines whether received data causes the display to scroll</td>
<td>true, false</td>
</tr>
<tr>
<td>TabSize</td>
<td>Integer</td>
<td>The spacing between fixed tab stops</td>
<td>1–100</td>
</tr>
<tr>
<td>TabStops</td>
<td>String</td>
<td>If variable tabs are used, a string where a T represents each tab</td>
<td>&quot;T     T     T     T&quot;</td>
</tr>
<tr>
<td>TabType</td>
<td>String</td>
<td>How tab settings are specified</td>
<td>Fixed, Variable</td>
</tr>
<tr>
<td>VT_PageAdvance</td>
<td>Boolean</td>
<td>Determines whether a received VT causes a page advance</td>
<td>true, false</td>
</tr>
</tbody>
</table>
## UTS Variables

UTS supports the following variables in AMUTS.PRE:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Specifies</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>AltBrightness</td>
<td>String</td>
<td>The way the cursor should blink</td>
<td>LowIntensity, Reverse, NormalIntensity</td>
</tr>
<tr>
<td>AlwaysHomeCursor</td>
<td>Boolean</td>
<td>Determines whether the cursor is placed at the home position even if it is protected</td>
<td>true, false</td>
</tr>
<tr>
<td>AutoShiftLB</td>
<td>Integer</td>
<td>The lower boundary for changing to uppercase or lowercase</td>
<td>1–255, indicating the character number</td>
</tr>
<tr>
<td>AutoShiftUB</td>
<td>Integer</td>
<td>The upper boundary for changing to uppercase or lowercase</td>
<td>1–255, indicating the character number</td>
</tr>
<tr>
<td>BeepOnSysMessage</td>
<td>Integer</td>
<td>Number of beeps when the host sends a message</td>
<td>0–99</td>
</tr>
<tr>
<td>BlinkEnabled</td>
<td>Boolean</td>
<td>Determines whether blink is enabled when the host sends a character with a blinking attribute</td>
<td>true, false</td>
</tr>
<tr>
<td>CPFlags:</td>
<td>Integer</td>
<td>Control page flags:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Display control characters</td>
<td>0x0001</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Destructive spaces</td>
<td>0x0002</td>
</tr>
<tr>
<td></td>
<td></td>
<td>System response mode</td>
<td>0x0004</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Upper case shift</td>
<td>0x0008</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Keyboard click</td>
<td>0x0010</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Intensity of status line (UTS 20/40)</td>
<td>0x0100</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Ignore host color (UTS 60)</td>
<td>0x0200</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Sound screen alarm (UTS 60)</td>
<td>0x1000</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Repeat screen alarm (UTS 60)</td>
<td>0x2000</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Cursor return (UTS 60)</td>
<td>0x4000</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Sets all values to their defaults</td>
<td>0x3312</td>
</tr>
</tbody>
</table>

**Note:** All apply to UTS 20/40/60 unless noted otherwise. For example, intensity of status line applies only to UTS 20/40.

To specify a combination of Control Page flags, add the values in the Value column. For example, to both display control characters and use a destructive space, set CPFlags = 0x0003.
### Chapter 7: Connection, Terminal, and File Transfer Tools

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Specifies</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>CursorShape</td>
<td>String</td>
<td>Shape of the cursor</td>
<td>block, underline, verticalbar</td>
</tr>
<tr>
<td>DefaultAppName</td>
<td>String</td>
<td>Name of host application specified in Windows registry</td>
<td>application_name</td>
</tr>
<tr>
<td>DNPartialEnd</td>
<td>Integer</td>
<td>The end line of a partial file transfer in a MAPPER download</td>
<td>line_number</td>
</tr>
<tr>
<td>DNPartialStart</td>
<td>Integer</td>
<td>The start line of a partial file transfer in a MAPPER download</td>
<td>line_number</td>
</tr>
<tr>
<td>DNPCFileMode</td>
<td>String</td>
<td>The file mode for a MAPPER download</td>
<td>append, overwrite, insert</td>
</tr>
<tr>
<td>DNPCFileType</td>
<td>String</td>
<td>The file type for a MAPPER download</td>
<td>csv, textwithtabs, textnotabs</td>
</tr>
<tr>
<td>DNSilentMode</td>
<td>Integer</td>
<td>MAPPER downloads in silent mode</td>
<td>1=silent mode, 0=off</td>
</tr>
<tr>
<td>DNStripHeader</td>
<td>Integer</td>
<td>MAPPER downloads stripping the header</td>
<td>1=strip header, 0=off</td>
</tr>
<tr>
<td>DynamicSizing</td>
<td>Boolean</td>
<td>Determines whether the font size changes with the session window size</td>
<td>true, false</td>
</tr>
<tr>
<td>EmphasisTransmit</td>
<td>String</td>
<td>Type of emphasis to transmit</td>
<td>emphxmit_none, emphxmit_e2, emphxmit_e3</td>
</tr>
<tr>
<td>ExtendedCP</td>
<td>Boolean</td>
<td>Determines whether the extended control page is enabled</td>
<td>true, false</td>
</tr>
<tr>
<td>FaceName</td>
<td>String</td>
<td>Font name</td>
<td>UTSFONT, PEFPONT, or a fixed-width typeface name, such as Terminal or Courier</td>
</tr>
<tr>
<td>FCCTransmit</td>
<td>String</td>

Appendix A  Error Messages

Classes of Error Message

The tables on the following pages list the error messages that might appear while you are compiling or running CASL macros, as well as possible solutions to these problems.

The following table lists error message classes and a description of each class. A class number precedes each error number.

## Internal Errors

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Error Message</th>
<th>Explanation</th>
</tr>
</thead>
</table>
| 10-08      | Internal error: Cannot find a connection, file transfer, or terminal tool. All tools must be installed to the frame directory before running Accessory Manager. | When you run Accessory Manager, it refers to the GI32.INI file for a list of installed connection, terminal, and file transfer protocols. There must be at least one of each. This error can occur under the following circumstances:  
  - No terminal emulator has been installed. Install a terminal emulator (such as UTS or T27) before running Accessory Manager.  
  - The GI32.INI file has been moved or deleted. Put a copy of the GI32.INI file in your Windows directory, or reinstall Accessory Manager.  
  - The GI32.INI file has been modified, and Accessory Manager cannot read it. Delete the GI32.INI file and reinstall Accessory Manager. |
| 10-12      | Internal error: Unknown GI error.                                               | An internal error has occurred. Contact Customer Support.                                                                                      |
| 10-49      | Internal error: Bad row number.                                                 | Your CASL macro has set an invalid row number. Edit the macro to ensure that the row number is valid.                                          |
| 10-50      | Internal error: Bad column number.                                              | Your CASL macro has set an invalid column number. Edit the macro to ensure that the column number is valid.                                   |
| 10-51      | Internal error: Bad length.                                                     | The length of data in your CASL macro is invalid. Edit the macro to ensure that the data length is valid.                                    |
| 10-96      | Unrecognized error code.                                                        | An internal error has occurred. Contact Customer Support.                                                                                     |
## Appendix A  Error Messages

### Compiler Errors

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Error Message</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>12-001</td>
<td>Too few arguments to procedure/ function 'procedure/ function name'.</td>
<td>When calling a previously defined function or procedure, you specified more arguments than you originally defined. Check the definition of the referenced procedure or function, and correct your macro.</td>
</tr>
<tr>
<td>12-002</td>
<td>Too many arguments to procedure/ function 'procedure/ function name'.</td>
<td>When calling a previously defined function or procedure, you did not specify all the arguments that you originally defined. Check the definition of the referenced procedure or function, and correct your macro.</td>
</tr>
<tr>
<td>12-003</td>
<td>Array 'array name' is too large.</td>
<td>Arrays are limited to a size of 32 KB. The referenced array exceeds that size. You can calculate the size of an array by multiplying the size of the data elements by the total number of elements in the array. Redefine the size of your array.</td>
</tr>
<tr>
<td>12-004</td>
<td>Invalid left hand side of assignment statement.</td>
<td>The operand on the left side of the assignment statement is invalid and cannot be assigned a value. This operand must be a variable. You cannot assign a value to a procedure, function, or constant. Correct the assignment statement and try again.</td>
</tr>
<tr>
<td>12-005</td>
<td>Bad combination of type modifiers.</td>
<td>The modifiers of this declaration are mutually exclusive. Modify the statement and try again.</td>
</tr>
<tr>
<td>12-006</td>
<td>No more cases allowed after the default case.</td>
<td>The default case must be the last value in a case statement. Check the structure of the case statement.</td>
</tr>
<tr>
<td>12-007</td>
<td>This format of the statement name statement is not supported in this version.</td>
<td>The statement in the macro is not supported or is incorrectly formatted. Refer to Chapter 5, &quot;CASL Language,&quot; for the correct syntax.</td>
</tr>
<tr>
<td>12-008</td>
<td>End of file was encountered in a comment.</td>
<td>The compiler reached the end of the source file while processing a comment. Check to see if the end-of-comment delimiter was accidentally deleted.</td>
</tr>
<tr>
<td>12-009</td>
<td>language element must be a compile time constant.</td>
<td>You must use a constant. You can not use a variable.</td>
</tr>
<tr>
<td>12-018</td>
<td>Duplicate declaration of 'variable'.</td>
<td>You have declared this variable twice. Only one declaration is allowed.</td>
</tr>
</tbody>
</table>
### Error Codes and Messages

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Error Message</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>12-019</td>
<td>Reference to undeclared variable 'variable'.</td>
<td>This variable has not been declared, and the compiler was unable to determine its data type from the context. Declare the variable in your macro.</td>
</tr>
<tr>
<td>12-020</td>
<td>Division by zero.</td>
<td>In evaluating the expression in this statement, you attempted to divide by zero. This is not allowed. Correct your macro and try again.</td>
</tr>
<tr>
<td>12-021</td>
<td>Unable to open file 'bad file'.</td>
<td>The compiler received an error when it tried to open this file. Check that the file name is specified correctly.</td>
</tr>
<tr>
<td>12-022</td>
<td>Error reading file 'bad file'.</td>
<td>The compiler encountered an error while trying to read this file. Make sure the file exists and is not damaged.</td>
</tr>
<tr>
<td>12-023</td>
<td>For loop needs assignment.</td>
<td>You did not set the initial value of the loop control variable in a for statement. Correct the for statement in your macro.</td>
</tr>
</tbody>
</table>
| 12-024     | 'procedure/ function name' was declared forward as procedure or function, not procedure or function. | One of two things occurred:  
- You declared this procedure or function as a procedure in the forward declaration, but defined it as a function in the actual definition.  
- You declared this procedure or function as a function in the forward declaration, but defined it as a procedure in the actual definition.  
Correct your macro so the forward declaration and the definition match. |
| 12-025     | Too few parameters to 'procedure/ function name' to match forward declaration. | The definition of this procedure or function has fewer parameters than its forward declaration. Make sure the forward declaration and the actual definition match exactly. |
| 12-026     | Too many parameters to 'procedure/ function name' to match forward declaration. | The definition of this procedure or function has more parameters than its forward declaration. Make sure the forward declaration and the actual definition match exactly. |
| 12-027     | Unresolved forward procedure or function 'procedure/ function name'.           | You made a forward declaration for this procedure or function, but you never provided an actual definition of it. Provide a definition for this procedure or function in your macro. |
| 12-028     | 'identifier' is not a function name.                                          | You have used an identifier as a function, but it is not a function. You must use a valid function name.                                  |
### Error Messages

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Error Message</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>12-029</td>
<td>genlabels directive must be on to use a computed goto.</td>
<td>At some point in your macro, you specified genlabels off. This directive must be on (its default state) to use the goto statement in a macro.</td>
</tr>
<tr>
<td>12-030</td>
<td>'identifier' is not a label.</td>
<td>You have used identifier as a label, but it is not a label. You must use a valid label.</td>
</tr>
<tr>
<td>12-031</td>
<td>Input statement needs a variable, not a constant.</td>
<td>You must specify a variable rather than a constant for the input statement. The input statement will use this variable to process keyboard input.</td>
</tr>
<tr>
<td>12-032</td>
<td>Internal error: compiler module line number.</td>
<td>An internal error has occurred in the compiler. Contact Customer Support and be prepared to furnish a copy of the macro that caused the error along with the exact information in this message.</td>
</tr>
<tr>
<td>12-033</td>
<td>Invalid time interval.</td>
<td>You specified a time interval incorrectly. Check the way you expressed the time.</td>
</tr>
<tr>
<td>12-034</td>
<td>Unresolved label: 'identifier'.</td>
<td>This label was never defined anywhere in your macro. Add the label to the appropriate section of your macro.</td>
</tr>
<tr>
<td>12-035</td>
<td>Lexical analysis error: specific error.</td>
<td>This error occurred during the lexical analysis phase of the compilation process. Check this section of your macro for syntax errors.</td>
</tr>
<tr>
<td>12-036</td>
<td>List box contents must be string or one-dimensional string array.</td>
<td>The variable that contains the list of items to be included in a list box must be either a string of items separated by commas or a one-dimensional array of strings.</td>
</tr>
<tr>
<td>12-037</td>
<td>Compiler out of memory.</td>
<td>The compiler ran out of memory while compiling your macro. Close any unneeded applications and try again.</td>
</tr>
<tr>
<td>12-038</td>
<td>Too many arguments to Nextline.</td>
<td>Too many arguments were specified for the nextline statement. Check the list of arguments you are passing to this statement.</td>
</tr>
<tr>
<td>12-040</td>
<td>Second operand of mod operator must be positive.</td>
<td>The modulus function allows only positive numbers for its second operand. Revise your statement to use a positive number.</td>
</tr>
<tr>
<td>12-042</td>
<td>Cannot have more than one OK or Cancel button.</td>
<td>A dialog box can have only one OK button and one Cancel button. Revise your macro accordingly.</td>
</tr>
<tr>
<td>12-043</td>
<td>Could not open module file 'bad file'.</td>
<td>Accessory Manager could not open the module file you specified. Make sure that the file name is correct and that the file resides in the proper location.</td>
</tr>
</tbody>
</table>
### Error Codes and Messages

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Error Message</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>12-044</td>
<td>Parsing error: specific error.</td>
<td>This error occurred during the syntactic analysis phase of the compilation process. Check this section of your macro for syntax errors.</td>
</tr>
<tr>
<td>12-045</td>
<td>Print format specification is not supported in this version.</td>
<td>Accessory Manager does not support print format specifications. Revise your macro to eliminate these specifications.</td>
</tr>
<tr>
<td>12-046</td>
<td>'identifier' is not a procedure name.</td>
<td>You have used an identifier as a procedure, but it is not a procedure. You must use a valid procedure name.</td>
</tr>
<tr>
<td>12-047</td>
<td>Exit can only be used inside a procedure.</td>
<td>The compiler encountered an exit statement outside of a procedure. Check the procedures and functions in your macro and make sure that they begin and end properly.</td>
</tr>
<tr>
<td>12-048</td>
<td>Return with value can only be used inside a function.</td>
<td>The compiler encountered a return with a value outside of a function. Values can only be returned from functions. Check the procedure and functions in your macro begin and make sure that they begin and end properly.</td>
</tr>
<tr>
<td>12-049</td>
<td>Exit cannot be used in a function.</td>
<td>The exit statement cannot be used to leave a function. It can only be used to leave procedures. Use the return statement instead of the exit statement in a function.</td>
</tr>
<tr>
<td>12-050</td>
<td>Return in a procedure cannot return a value.</td>
<td>Procedures cannot return values. The return statement is used to return a value inside a function. Either redefine your procedure as a function, or change the return statement in your procedure.</td>
</tr>
<tr>
<td>12-051</td>
<td>Bad use of '^' in string constant.</td>
<td>The caret symbol followed by a control character indicates an unprintable control character in a string constant. The character following the caret is not a valid control character. Check the character following the caret in the string constant.</td>
</tr>
<tr>
<td>12-052</td>
<td>String constant too long.</td>
<td>The maximum length of a constant is 256 characters. Shorten your string to fit within this limit.</td>
</tr>
<tr>
<td>12-053</td>
<td>String subscript out of range.</td>
<td>The subscript you specified to access a character in this string is beyond the end of the string. Make sure the subscript is within the bounds of the string.</td>
</tr>
<tr>
<td>12-054</td>
<td>Too few subscripts to array name.</td>
<td>You have not specified enough subscripts to reference this array. You specified more dimensions when you declared the array than you used when you referenced it. Correct either the declaration or the reference.</td>
</tr>
</tbody>
</table>
## Error Messages

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Error Message</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>12-055</td>
<td>Too many subscripts to array name.</td>
<td>You have specified too many subscripts to reference this array. You specified fewer dimensions when you declared the array than you used when you referenced it. Correct either the declaration or the reference.</td>
</tr>
<tr>
<td>12-056</td>
<td>Syntax error at 'bad token'.</td>
<td>The compiler found an error in your macro near bad token. Make sure that all language elements in this section of your macro are specified properly.</td>
</tr>
<tr>
<td>12-057</td>
<td>Bad token: 'string'.</td>
<td>The compiler did not recognize a string in your macro. Make sure that all language elements in string, and in the instructions surrounding it, are specified properly.</td>
</tr>
<tr>
<td>12-058</td>
<td>Track procedure cannot take parameters.</td>
<td>The procedure you named to the track statement cannot have any parameters. Make sure that both the track statement and the procedure definition are specified properly.</td>
</tr>
<tr>
<td>12-059</td>
<td>Track procedure cannot be a function.</td>
<td>The procedure you named to the track statement must be a procedure, not a function. Make sure that both the track statement and the procedure definition are specified properly.</td>
</tr>
<tr>
<td>12-060</td>
<td>Track procedure can only be a label or user procedure.</td>
<td>The procedure you named to the track statement may only be a procedure or a label. Make sure that both the track statement and the procedure definition are specified properly.</td>
</tr>
<tr>
<td>12-061</td>
<td>Type error: Assume file name must be a string constant.</td>
<td>The file name you specified in the assume statement must be a string constant, not a variable. Make sure that the name is a string and a constant.</td>
</tr>
<tr>
<td>12-062</td>
<td>Type error: cannot perform &quot;operator&quot; on types type 1 and type 2.</td>
<td>This operation cannot be performed on variables of these types. Check the operation and make sure that the operands are of compatible types.</td>
</tr>
<tr>
<td>12-063</td>
<td>Type error: case selector cannot be bad type.</td>
<td>The type specified in the message cannot be used for the selector in a case statement. Use a different type for the selector.</td>
</tr>
<tr>
<td>12-064</td>
<td>Type error: cannot convert type 1 to type 2.</td>
<td>The compiler cannot convert the values specified. Check the operation and make sure that the operands are of compatible types.</td>

</table>
### Appendix A Error Messages

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Error Message</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>12-065</td>
<td>Type error: &quot;string&quot; cannot be converted to type.</td>
<td>The compiler encountered an error when attempting to convert this string into type. This conversion was required by the usage of the string in your macro. Make sure the value in this string is compatible with the data types required by this statement. Perhaps a string is not required in this case and some other data type could be used.</td>
</tr>
<tr>
<td>12-066</td>
<td>Type error: language element must be good type, not bad type.</td>
<td>You used an invalid type for language element. You must use the type specified in good type.</td>
</tr>
<tr>
<td>12-067</td>
<td>Type error: language element must be a type variable.</td>
<td>You used an invalid type for language element. You must use a variable of the type specified in type. A constant is not allowed in this situation.</td>
</tr>
<tr>
<td>12-068</td>
<td>Type error: Parameter number of 'procedure/ function name' was declared forward as good type, not bad type.</td>
<td>In the forward declaration of this procedure or function, this parameter was declared to be of a different type than in the actual definition. Make sure the forward declaration and the actual definition match exactly.</td>
</tr>
<tr>
<td>12-069</td>
<td>Type error: Return type of 'function name' was declared forward as good type, not bad type.</td>
<td>In the forward declaration of this function, the return value was declared to be of a different type than in the actual definition. Make sure the forward declaration and the actual definition match exactly.</td>
</tr>
<tr>
<td>12-070</td>
<td>Type error: colors must be integer or specific color names.</td>
<td>You must either use an integer expression or specific color names, such as &quot;red,&quot; to specify a color.</td>
</tr>
<tr>
<td>12-071</td>
<td>Type error: argument number of procedure or function 'procedure/ function name' must be good type, not bad type.</td>
<td>One of the arguments for this procedure or function is of the wrong type. Check the definition of the procedure or function and make sure that you are calling it properly.</td>
</tr>
<tr>
<td>12-072</td>
<td>Type error: cannot subscript variable.</td>
<td>This variable is not an array variable and cannot be subscripted. Either declare the variable to be an array, or use an existing array variable.</td>
</tr>
<tr>
<td>12-073</td>
<td>Type error: subscript 'number' of 'array name' must be good type, not bad type.</td>
<td>This subscript is of the wrong type. Make sure the subscript is of the type specified in good type.</td>
</tr>
</tbody>
</table>
### Error Messages

<thead>
<tr>
<th>Error Code</th>
<th>Error Message</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>12-074</td>
<td>Type error: subscript 'string name' must be good type, not bad type.</td>
<td>This subscript is the wrong type. Make sure the subscript is of type specified in good type.</td>
</tr>
<tr>
<td>12-075</td>
<td>Type error: cannot perform 'operator' on type bad type.</td>
<td>This operation cannot be performed on a variable of bad type. Check the operation and make sure that the operand's type is compatible with the operation.</td>
</tr>
<tr>
<td>12-076</td>
<td>Type error: procedure must be a user procedure.</td>
<td>A user-defined procedure is required here. You cannot use a CASL built-in procedure.</td>
</tr>
<tr>
<td>12-077</td>
<td>The number of buttons is limited to four.</td>
<td>An alert box can have only four buttons. You have tried to put too many buttons in your box. Limit the number of buttons to four.</td>
</tr>
<tr>
<td>12-078</td>
<td>Statement or expression is too complex.</td>
<td>This statement or expression is too complex for the compiler to compile. Simplify the statement or expression, or break it up into smaller parts.</td>
</tr>
<tr>
<td>12-079</td>
<td>Type error: cannot assign right-side type to left-side type.</td>
<td>The type of expression on the right side of the assignment statement is not compatible with the variable on the left side. Correct the assignment statement to make the types agree.</td>
</tr>
<tr>
<td>12-080</td>
<td>Error writing file 'bad file'.</td>
<td>The compiler received an error from the file system when it tried to write to the specified file. Possible reasons for this error are as follows:</td>
</tr>
<tr>
<td></td>
<td>- Your disk is full. Free up space on this disk or use another disk.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- You have too many files open in other applications. Close any applications you are not using.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- Your disk is bad. Check to make sure your disk is not damaged.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- A removable disk or a network disk is no longer online. Make sure the disk you are trying to write to is online.</td>
<td></td>
</tr>
<tr>
<td>12-081</td>
<td>String constant must be one line.</td>
<td>A string constant must be entirely on one line. It cannot extend across multiple lines. Your string is too long. Make sure the string has a closing quotation mark.</td>
</tr>
</tbody>
</table>

<tbody>
<tr>
<td>13-05</td>
<td>The file number is invalid or missing.</td>
<td>Make sure you specify a file number in the get, put, read, and write statements. You must precede the number with the pound symbol (#).</td>
</tr>
<tr>
<td>13-06</td>
<td>The specified file channel number is already open. You must first close the channel or use another one.</td>
<td>The specified file channel number is already open. You must first close the channel or use another one.</td>
</tr>
<tr>
<td>13-07</td>
<td>The specified channel number is not open.</td>
<td>You tried to manipulate a file using read, write, get, or put without first opening the file, or the file was previously closed. Open the file before using read, write, get, or put.</td>
</tr>
<tr>
<td>13-08</td>
<td>Accessory Manager cannot read an output file.</td>
<td>You opened this file for output only and tried to issue a read or get statement. Modify your macro and try again.</td>
</tr>
<tr>
<td>13-09</td>
<td>Accessory Manager cannot write to an input file.</td>
<td>You opened this file for input only and tried to write to it using the write or put statements. Modify your macro and try again.</td>
</tr>
<tr>
<td>13-10</td>
<td>Accessory Manager cannot get/put a text file.</td>
<td>You opened the file for input or output. These are read and written to sequentially using the read and write statements. Use get and put for random files.</td>
</tr>
<tr>
<td>13-11</td>
<td>Accessory Manager cannot read from or write to a random file.</td>
<td>You opened the file in random mode and tried to use the read or write statements. Use get and put for random files.</td>
</tr>
<tr>
<td>13-16</td>
<td>Window coordinates out of range.</td>
<td>The coordinates you have specified for accessing a window are not valid. The coordinates must access a valid portion of the window or display.</td>
</tr>
<tr>
<td>13-18</td>
<td>The specified window is not open.</td>
<td>You have specified a window that is not open. You cannot perform operations on a window unless it is open.</td>
</tr>
<tr>
<td>13-28</td>
<td>Attempt to send output to the display failed.</td>
<td>An error occurred while Accessory Manager was trying to write information to the screen. Try running the macro again. If it still fails, exit Accessory Manager and/or Windows and try again.</td>
</tr>
</tbody>
</table>
### Appendix A Error Messages

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Error Message</th>
<th>Explanation</th>
</tr>
</thead>
</table>
| 13-29      | A file copy failed. | Accessory Manager was unable to copy a file. The following are possible reasons for this error:  
  - Your disk is full. Delete unneeded files and try again.  
  - You have too many files open in other applications. Close the open files and try again.  
  - Your disk is bad. Contact your system administrator.  
  - A removable disk or a network disk is no longer online. Try again when the specified disk is online. |
| 13-30      | The script attempted a seek in a sequential file; you can use seek only with random files. | The file was not opened properly for performing the seek function. Open the file using the appropriate mode. |
| 13-31      | Multiple windows in a session are not supported in this version. | This feature is not currently supported. Revise your macro to use other language elements. |
| 13-32      | An error has occurred in attempting to create a new window. | An error occurred with the `new` command in your macro. If you are using this command to open an existing session, be sure to specify the file name of the existing session. |
| 13-33      | There is already a file that has the name selected. | You must use a unique name for each file. Change the file name and try again. |
| 13-48      | File creation error. | Accessory Manager was unable to create a file. Verify that you have adequate space on your disk and that you have write privileges. |
| 13-64      | You must use `-k` or `-c` when using `-p` command line parameter. | The `-p` command line parameter specifies which INFOConnect path to use for a particular session. You must first open a session using the `-k` or `-c` command line parameters before you can specify a path for the session. |
| 13-65      | The caption specified is too long. It will be truncated. | The caption specified for the session window title bar is greater than 128 characters. Accessory Manager will truncate the caption unless you reduce its size. |
| 13-66      | Administration utility file not found. See your administrator for further instructions. | If the file `AMFULL.RCF` is not in the Windows directory, Accessory Manager cannot run. Copy this file to the Windows directory, or reinstall Accessory Manager. |
## Mathematical and Range Errors

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Error Message</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>14-03</td>
<td>Division by zero was attempted.</td>
<td>You tried to divide by 0. Check your macro, and the expression used for the divisor, to determine why the divisor contained a value of 0.</td>
</tr>
<tr>
<td>14-05</td>
<td>The expression is not valid for the variable.</td>
<td>You tried to assign a different variable type to this variable. Be sure to use valid expressions for each variable.</td>
</tr>
<tr>
<td>14-06</td>
<td>The value is outside the permissible range.</td>
<td>You specified a range for the indexes in an array variable. The index falls outside that range.</td>
</tr>
<tr>
<td>14-09</td>
<td>A string was truncated.</td>
<td>Accessory Manager truncated a string because it was too long. Strings can be up to 32 KB.</td>
</tr>
<tr>
<td>14-10</td>
<td>Invalid characters were found in a numeric string.</td>
<td>You tried to make an assignment to an integer value. The expression contained alphabetic or non-numeric characters. If you are using hexadecimal representation, make sure the number ends in h.</td>
</tr>
<tr>
<td>14-11</td>
<td>The specified value is outside the acceptable range.</td>
<td>You specified a range for the indexes in an array variable. The index falls outside that range. Increase the size of the array. If you are using a variable for the index, make sure that the variable contains a value inside the defined array range.</td>
</tr>
<tr>
<td>14-18</td>
<td>An invalid string was specified for the quote function.</td>
<td>A string specified for the quote function cannot contain both single and double quotation marks. Make sure that both types of marks are not used in the string you pass to the quote function.</td>
</tr>
</tbody>

</tr>
<tr>
<td>16-12</td>
<td>A read fault has occurred.</td>
<td>Accessory Manager could not find the specified data. Use the CHKDSK utility to make sure your disk has not been corrupted.</td>
</tr>
</tbody>
</table>
## Macro Execution Errors

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Error Message</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>17-01</td>
<td>The specified label cannot be found.</td>
<td>Make sure the label you specified in the <code>golib</code> or <code>goto</code> statements has a corresponding label statement where you want it to go. Labels are not case-sensitive.</td>
</tr>
<tr>
<td>17-03</td>
<td>'gosub' statements are nested too deep.</td>
<td>You can have only a certain number of <code>gosub</code> statements without issuing a return. Refer to Chapter, “CASL Language,” for the correct syntax.</td>
</tr>
<tr>
<td>17-05</td>
<td>A data type mismatch for an external variable was found.</td>
<td>You are referencing a variable declared in another macro. Check the other macro for the appropriate data type for that variable.</td>
</tr>
<tr>
<td>17-07</td>
<td>The script was canceled by the user.</td>
<td>This is an informational message. You can run the macro again.</td>
</tr>
<tr>
<td>17-08</td>
<td>A reference to an unresolved external variable was found.</td>
<td>This variable is declared as external in this macro. It must be declared as public in a macro that calls this macro using the <code>do</code> statement.</td>
</tr>
<tr>
<td>17-10</td>
<td>An unavailable module variable was found.</td>
<td>The module in the <code>assume</code> statement is not yet loaded. Use the <code>device</code>, <code>terminal</code>, or <code>protocol</code> system variables to load a given tool. The <code>assume</code> statement only makes these variables and settings known to the compiler; it does not load the tool to make it accessible to running macros.</td>
</tr>
<tr>
<td>17-12</td>
<td>A 'return' statement without a corresponding 'gosub' statement was found.</td>
<td>While executing the macro, a <code>return</code> statement was encountered, but the macro is not in a <code>gosub</code>. There may be a logic error in the macro. Examine the logic of the macro carefully and revise it.</td>
</tr>
<tr>
<td>17-14</td>
<td>A script compilation failed when 'chain', 'do', or 'compile' statement was executed.</td>
<td>When a <code>chain</code>, <code>do</code>, or <code>compile</code> statement is issued, Accessory Manager checks to see if the macro needs compiling. If it does, Accessory Manager recompiles it before it runs. This error message appears when a macro is compiled in this manner, but has an error and cannot continue. Use the CASL Macro Editor to correct errors in the macro, and try again.</td>
</tr>
<tr>
<td>17-15</td>
<td>A return value was missing in the return from a function.</td>
<td>You declared a function, but never used the return statement to return a value. The value must be the same data type you used when you declared the function.</td>
</tr>
</tbody>
</table>
### Appendix A  Error Messages

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Error Message</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>17-16</td>
<td>Generic error.</td>
<td>This error can occur when the PC is out of memory. Close any unneeded applications, and try again.</td>
</tr>
<tr>
<td>17-17</td>
<td>An internal error occurred. Delete the .xwc file and recompile the script.</td>
<td>The .XWC file has become corrupted. Delete the file and recompile the macro.</td>
</tr>
<tr>
<td>17-18</td>
<td>An invalid count expression was used.</td>
<td>The count expression used in this statement is not valid. Correct this portion of the statement.</td>
</tr>
<tr>
<td>17-19</td>
<td>A string expression is too long.</td>
<td>Strings are limited to 32 KB in size. Change the logic of your macro so that you do not create strings exceeding this length.</td>
</tr>
<tr>
<td>17-20</td>
<td>There is not enough global memory available.</td>
<td>Accessory Manager does not have enough memory to perform the function. Try closing sessions, QuickPads, and other windows that you are not currently using.</td>
</tr>
<tr>
<td>17-21</td>
<td>A 'dialogbox' keyword was used outside a 'dialogbox' statement.</td>
<td>The keywords which describe a dialog box can only be used inside a dialogbox statement. Revise your macro to eliminate this occurrence of the keyword.</td>
</tr>
<tr>
<td>17-22</td>
<td>'dialogbox' statements are nested. These statements cannot be nested.</td>
<td>Revise your macro to eliminate nested dialogbox statements.</td>
